Original Articles.

THE MEDICAL PROFESSION AND ITS WORK IN INDIA, PAST, PRESENT AND FUTURE.

BEING THE ADDRESS OF SURGEON-COLONEL ROBERT HARVEY, M.D., F.R.C.P., F.O.C., V.H.S., D. S. O.

The President of the First Indian Medical Congress.

YOUR EXCELLENCY, your Honor, my Lords, Ladies and Gentlemen!—The first duty which devolves upon me is the pleasing one of conveying to your Excellency on behalf of the Central Committee, and I may say of every member of this Congress, our hearty thanks to your Excellency for the honor you have done us in presiding on this occasion. We take it, and the world will take it, as a proof that the Government of India is anxious and willing to do what in it lies to favor the objects which this Congress has at heart—objects which have no political significance, but which are of consummate interest to the well-being and prosperity of India. The medical profession, as such, is of no politics, its objects are to battle with disease, to relieve suffering, save life, and promote the health and welfare of the people; ends with which all should sympathise, and towards which all can help. The Congress, by bringing together from all parts of the country all sorts and conditions of medical men and women, European and Indian, official and non-official, civil and military, private practitioners, medical missionaries and others, tends to establish a solidarity of interests and aims which is devoutly to be wished for, and to strengthen the influence of the profession by concentrating it in one broad current. It brings men into close and kindly personal relations, cements old, and lays the foundations of new friendships, enables us to compare experiences, and puts on permanent record much valuable material which is now lost for want of a chronicler. When the idea of a Congress was first started, there was considerable doubt as to whether India was sufficiently advanced to be able to make it a success, and many difficulties were pointed to by cautious men. The Committee and the Secretaries, however, accepting the Napoleonic definition of a difficulty, as something to be overcome, and feeling sure that success was attainable, proceeded to attain it. *Si monumentum queris circumspice.* You have but to look at this meeting to see the monument of their success, and the programme of work to be got through is such that I greatly fear many papers will have to be taken as read. Our total membership is nearly 500. Two hundred and odd papers have been sent in, many of them of the very highest professional and public interests, involving discussions of supreme importance both to the public health and to the public pocket. The success, of which we are now assured, is due in part to the exertions of the Central and Executive Committees, in part to the unwearied exertions of the general Secretaries, in part to the kindness and good-will of the Government in granting facilities for attendance, and to the splendid hospitality of the reverend fathers who have placed this great College at our disposal. It is, however, mainly, and above all, due to the fact that the profession has been true to itself and to its own best traditions. Nothing but

good can come from such a meeting, and I trust that this, the first Indian Medical Congress, may be followed every three or four years by many others to the advantage of the profession and of this country. I have, on the part of the Central Committee, to extend a warm welcome to the delegates who have come to us from other countries. They are all too few, but the exigencies of medical work in the busy season at home has kept many away, and the length and supposed difficulties of the voyage have detained others.

I will now try to indicate in the briefest way what modern medicine has done, is doing, and may hope in the future to do for India. The subject is so vast that it can be given in outline and no more, a mere scene painter's sketch, not a finished picture. By modern medicine I, of course, mean the science introduced from Europe by the earliest medical officers of the Honorable East India Company. From the small beginnings made by them has developed by natural evolution our system of hospitals and dispensaries, sanitation, vaccination, and medical education as they exist to-day, and from which we hope that a further development may take us in time to things unattempted yet.

It is a curious fact that it was in gratitude to a doctor envoy for professional services that the first firman was granted to the Company, by the Emperor Jahangir. In the earlier days of the Company, and, in fact, up to the evil times of 1857, and to some extent even yet, we find medical officers in the most incongruous and unexpected positions and places—Residents and Envoys at foreign Courts—Commissioners and Deputy Commissioners, Superintendents of Gun-powder Factories—Post-masters General, heads of such departments as the Telegraph, Masters of Mints and so on. This, I take, was due in great measure to the fact that in the earlier days both civilians and military officers came out so young that they were beaten in the advantages education gives, by the older and more scientifically trained medical officers. The medical science of that day we should now look upon as very primitive, but it was the best that was to be had, and did yeoman's service to the Company and the people. As the red boundary line of England's influence extended, dispensaries and hospitals sprang up in all the large cities, and brought relief to many, specially surgical relief. The idea of preventive medicine had not yet been born, even in England, so that no sanitary service was attempted. Vaccination was, however, started within two years of its discovery by JENNER, and a beginning was made with medical education. From a very early time, native doctors, as they were then called, were trained at the local dispensaries, beginning as apprentices or even as hospital coolies, picking up what they could at the best side, aided by informal teaching from the Civil Surgeon. The results, strange as it may seem, were sometimes surprisingly good. I have seen lithotomy and cataract operations ideally perfect in technique, finish and result, performed by a man who had never attended a medical school and knew next to nothing of Anatomy. As a rule, however, the results were not satisfactory, and an enormous advance was made, when in 1822 a vernacular medical school was started in Calcutta. Systematic medical education really began, however, with the opening of the

Medical College of Bengal in 1884, followed by that at Madras in 1885, and at Bombay in 1888. In all these the instruction was in English. The Vernacular Medical School in Calcutta was followed by one at Hyderabad founded in 1846, another at Agra in 1855, and one at Lahore in 1880. When I came to India in 1865 these were the only schools.

I tried to get for this address a statistical statement shewing the chief medical and surgical results obtained throughout India in 1865. The first year for which complete statistics are available is, however, 1877. If the progress between 1865 and 1877 was at the same rates as between 1877 and 1893, we should have to halve the figures of 1877 to arrive at those of 1865. In 1877 then 6,142,070 patients were treated in 1147 hospitals and dispensaries; 4,633,105 vaccinations were performed, 2,682 operations for stone and 2,372 for cataract. These were great results and reflect the utmost credit on the officers who attained them; but they were nothing in relation to the population and true needs of the country. Small tentative efforts had been made to introduce sanitary improvements—I am now speaking of 1865—but systematic sanitation, as we know it, had not begun. The Sanitary Department, though its formation was under consideration, had not been constituted, and the death-rate of the European troops had from the beginning of the century reached the appalling annual average of 69 *per mille*. A Royal Commission sitting in 1864 ventured to express a hope that the introduction of scientific sanitation might reduce this to 20 *per mille*, and the creation of the Sanitary Department as a result of their recommendations may be taken as a boundary line dividing the past from the present of medical work in India.

My period of service, now close on 30 years, coincides with this. It has been marked by enormous progress in all directions. Medical colleges, in which a complete education is given in English, have been opened at Lahore, Allahabad, Tanjore, Nellore and affiliated to the Universities. At Hyderabad the classes have been taught in English since 1882. Additional vernacular medical schools for the education of Civil Hospital Assistants and civil medical practitioners are now working at Sealdah, Patna, Dacca, Cuttack, Poona and Ahmedabad.

The medical education of women has also been recently introduced, and girls are now trained for the purposes of the Dufferin Fund at most of the medical schools. The number of hospitals and dispensaries open last year was 2,025, at which were treated 16,973,468 patients, increases of 76 and 176 per cent. over 1877. There were 4,476 operations for stone, 20,279 for cataract. Vaccination has been enormously extended and put on a much more systematic footing, 7,602,024 operations were done, an increase of 63 per cent. These figures indicate great activity and afford ground for congratulation, yet compared with the wants of the country, they still touch but the fringe of the population. In Bengal, for instance, only one-fifteenth of the people are within five miles of a dispensary, and a considerable percentage of the children born escape vaccination, so that bad epidemics of small pox are still possible. Of recent years an entirely new development has taken place in the

organisation of special hospitals for women, offered by medical women, under the fostering care of the noble LADY DUFFERIN, whose name like MILTON's should resound for ages among the zenanas of India. Still in its infancy, it is doing enormous good to a class whose needs are of the sorest, and it is, I believe, destined to flourish and increase till every important town in India has its Dufferin Hospital side by side with its hospital for males.

Sanitary progress, however, is the chief feature of the last 30 years, and more especially of the last decade. I have told you how the death-rate of British soldiers up to 1857 averaged 69 *per mille*, and that the Sanitary Commission ventured to hope it might be reduced to 20. This estimate was too modest, for since 1882 it has never exceeded 15, except in 1889, when it was 15.6, less than a quarter of the previous rate. The reduction has been affected by hygienic reforms of all kinds, but especially by the gradual improvement of the water-supply in cantonments, first by cleaning and protecting wells and tanks and setting them aside for drinking purposes only, a plan which has been followed for many years; and of recent years by scientifically devised water-works provided with all the latest improvements. A glance at the two maps I shew you, will give a better idea than any words can of the great recent advances in this direction. The first representing the India of 1865 is like the Chart of the Shark-hunters "a perfect and absolute blank." The second shews the cities, towns and cantonments now properly supplied, or in course of being supplied with pure water. In those with dotted lines the works are in hand, but not yet in operation. The Cawnpore works are complete in the town, but have not yet been extended to the cantonment. The Murree water scheme supplies Dunga Gali, Kyra Gali, Bawan, Kuldanna, Clifden, Gharial and Thop as well as the Murree Bazar, cantonment and civil station. It cost Rs. 7,20,000. The whole of the troops in the hills near Murree, numbering some 5,000, are thus supplied with pure water. Many additional schemes are under consideration.

It has long been the fashion to poke fun at the Sanitary Department, to denounce it as a sham and a pretence, producing reports which lead to nothing—*Vox et præterea nihil*—and sanitary officers themselves have sometimes felt that much of their labor was of the Sisyphæan sort in the absence of any means to enforce and carry out their recommendations. The map seems to me to point to encouragement instead of despair. Even in England modern sanitation is a thing of the present century—mainly of the last half century—sanity has not been reached and popular ignorance and prejudice and vested interests still block many possible improvements. In India where *stare super vias antiquas*? What was good enough for our fathers is good enough for us, is a sentiment deep rooted in the hearts of the people, and is almost a part of their religion; it is small wonder that the progress has been slow. Still the progress is there, and in India as elsewhere, tends to acquire continually increasing force and volume as it proceeds.

Municipal Acts containing provision *inter alia* for sanitary measures, Village Sanitation Acts specially designed *ad hoc*, have been embodied in our laws, and though

mainly permissive, can be extended by notification to such places as seem sufficiently advanced to accept them.

Sanitary Boards on which a Sanitary Engineer are now established in most provinces. Various schemes are on foot for extension of water-works, drainage and other improvements. The importance of sanitary measures is now much more fully recognised than it was even a few years ago; so are the obligations of Governments to deal with preventable diseases; the latter fact finding practical expression in the greatly-improved arrangements for the regulation of the great religious gatherings at Hardwar and elsewhere, the supervision of pilgrim traffic, and so on. To cynics and pessimists who object that what has been done is as nothing to what remains to do, I can only say with TENNYSON, "Wait, my faith is large in time." Sanitation is in the air, and my successor in this chair 30 years hence will, I venture to think, be able to announce progress still greater than has been made since 1865.

SAM SLICK has warned us not to prophesy unless we know. I will not prophesy, but will now try to indicate a little more fully in what directions progress is likely and desirable, the difficulties in the way, and the means of overcoming them. No one is more thoroughly aware than I how little the great deal that has been done is, compared with what is left to do, and no one can recognise more fully the difficulties in the way of affecting such a general reform as shall satisfy Europe. When asked what India wants from medical and sanitary science, I am tempted to use the words of the ragged urchin in *Punch* who replied to a similar question, "I think I wants most everything." Let me enumerate the needs, first medical, then sanitary. We will take the question as to the means of providing for them later. The first and greatest is like Cerberus three-headed. To bring the advantages of modern medicine within reach of all, we require a great extension of hospitals and dispensaries, officered by a class of locally-trained practitioners of higher professional attainments than the average of those educated at existing schools. This in turn involves improved facilities for teaching, by bringing the schools up to date in method and equipment, raising the educational standards and improving the position of the graduates and licentiates. I have mentioned that only one-fifteenth of the population of Bengal is within a reasonable distance of a dispensary. Other provinces are in advance of Bengal, and the N.-W.-P. do not intend to be content till they have a dispensary within five miles of every one. If the principle is to be generally applied, the personnel of the Medical Department will have to be largely increased, and will even then have to be supplemented by the labors of a vast number of independent practitioners. I consider, however, that till we have an improvement in the standard of medical education, any great immediate increase in the number of dispensaries is not desirable. Itinerant dispensaries, such as have been provided in the Native State of Gondal at the trifling annual cost of Rs. 1,300 each, might be helpful for a time, but are at best a makeshift. As an old teacher and examiner, I think that the medical education already given is as regards the great colleges which teach in English,

marvellously good, and that many of our Native graduates are fit to hold their own with men educated in any land. The results achieved in some instances by the vernacular schools are also surprising, and have greatly improved of recent years. Neither English nor vernacular schools, however, are as efficient as they should be. The Medical College of Calcutta, the parent of all subsequent medical schools, is most miserably and inadequately housed. It has but two poor theatres in which lecture has to succeed lecture without intermission, so that the professors have neither the time nor the opportunity to prepare for their demonstrations, and the rooms are poisoned by the mephitic air of a succession of audiences. There is no room for the professors, not even a lavatory in which to wash their hands. Continuous efforts have been made to keep the teaching equipment in line with modern progress, and with fair success, but the laboratories, dissecting-room, anatomical and other departments are all cramped for space, and so damp and dark and ill-arranged that effective teaching is very difficult. It is far behind the schools in Bombay, Madras, and Lahore, and in some respects even behind the Vernacular School at Agra. Most of the vernacular schools are equipped on a scale so modest that the wonder is they can attain such results as they do, which must be ascribed to the diligence and good-will of both teachers and students. Recommendations have recently been made which, if accepted by Government, will give improved facilities for teaching and will improve also the position and prospects of such of the licentiates as enter the service of Government. Though still capable of improvement, the success in medical education in India has been phenomenal, and for a time the supply of practitioners has almost outrun the demand. Competition is severe and opportunities of attaining distinction limited, since Government naturally appoints its own servants to its own hospitals and teacher-ships. The services are open to all, but admission to the commissioned ranks involves a sojourn in England with a severe competitive examination at the end of it, and the local service, while also limited, has so few real prizes that it is not in great request. An outlet which would meet the natural aspirations of a most deserving class of men is greatly needed, and will, I believe, be found as the number of hospitals increases and the Health Department is strengthened. The bulk of practitioners must, however, still look to private practice, and as education spreads, the demand for their services is constantly increasing. The Government in India does more than any Government in the world to provide medical aid for its subjects, but no Government can give employment to all comers. The local profession, if I may venture to say so, wants a little more self-help and self-reliance. The School of Medicine recently established in Calcutta, independent of Government aid, is a step in the right direction, and when hospitals are built and maintained in India as in England by voluntary contributions, the contributors will naturally elect their own officers. They are empowered to do so under existing regulations, and 129 of the dispensaries of Bengal are at present officered by medical men elected by the committees. The difficulties and limitations of private practitioners have my

warmest sympathy. I have always done and will always do my best to help them, but so long as the great hospitals and medical schools are maintained by Government, it is reasonable that they should be officered by Government servants, and so long as Government continue to get the best men they can by open competition of the severest kind, I fail to see that there is any valid reason for complaints. As SHAKESPEARE says :

The remedies oft in ourselves do lie

Which we ascribe to heaven,

and the remedy here lies in private enterprise uncontrolled by Government ; though in all probability aided and fostered by Government, which is always ready to help those who help themselves. A new hospital is to be built in Calcutta by Government. I have recommended that on certain conditions it shall be governed by trustees and officered by non-officials, but have distinctly said I do not recommend it if the extra cost involved is to fall on the Government. That extra cost should be raised without difficulty if there is any real desire for the new departure. We meet you more than half way, do you for your own selves the rest.

Another need felt greatly by the profession is that of some such Act as the Medical Acts of England, by which properly-educated and duly-qualified men may be distinguished from the hosts of quacks, charlatans and imposters who everywhere abound. It is not to be expected that the State can put down or try to put down quackery, but it would be something to be able to tell regular practitioners from the predatory free lances and if, in addition to a register, some body analogous to the Medical Council of England were appointed, another advantage would be gained, and it would be possible to elevate and improve the condition of the profession by purging it of those members—few and yet still far more common than they ought to be—who disgrace themselves and help to degrade medicine by public advertisements, the issue of obscene catalogues and other objectionable practices.

The elimination of such persons would raise the tone of the whole profession and improve our ethical standards, which are much too low. We want to see less of the trade and more of the scientific element, and while it is no doubt true in spite of TALLYRAND, that a man must live, he must not *proper vitam vivendi perdere causas*, for the sake of life give up all that makes life worth living. Fine phrases as to the dignity of our noble profession, the unity of its interests, the catholicity of its aims are mere pickings from the waste-basket of words in the mouth of a man who will steal his neighbour's patient and blast his good name with a sneer. The too credulous public whom every sophister can blind are mainly to blame for the constant changes of medical attendants so common in India, but if medical men were less ready to humour them, and more "apt to point out the foolishness" of what LUXFORD called swapping horses in mid-stream, it would be good for both patient and practitioner.

Another great and crying need, both for the profession and the public, is the extension to India of those modern discoveries which are so fruitful for good in Europe, and which have such splendid potentialities of future development. It is not creditable that India, whose crowded

millions are as interested as any in the solution of the problems of disease, and the provision of medicine, should be doing nothing to bring about such desirable results. It is not to the credit of England that when the plague breaks out in a Crown Colony, she should be dependent on a country like Japan for a demonstration of the cause of it. It has often been a reproach to Indian medical men that with all their vast opportunities they have done little for pathology. The charge is in the main true, though brilliant exceptions might be mentioned but the explanation is not far to seek. No man can serve two masters, and officers liable to transfer from one end of India to another at the shortest notice, with hospital and private work filling their time and causing constant interruptions, cannot if they would give the close attention which is necessary to successful pathological work. Modern pathology, including bacteriology, demands the whole time of its votaries, and laboratories filled with costly instruments and appliances. There is work in abundance for many observers, but the scheme of the Government Medical Department hardly contemplates such, and here, too, we must look mainly to private enterprise, though Government may well be asked to aid. I have long been pleading for a thorough scientific investigation of Indian fevers. Years ago I recorded my opinion that one or possibly more specific fevers are mixed up together with those recognised in the official nomenclature. The working out of this point is of supreme importance to India, where some 75 per cent. of the recorded deaths are ascribed to fever, but it cannot be done without especial research. Diphtheria is a very fatal and destructive disease. A new mode of treatment, which has already been tried on an extensive scale, promises to reduce the mortality by one-half. Yet this treatment cannot be made available to the people of India until facilities for carrying it out are provided. Persons bitten by rabid animals have to go to Paris for treatment. All these needs will be met, and India take her proper place among those countries which are trying to advance science for the benefit alike of men and animals, when the Pasteur Institute of India is established. That institute we mean to have, and to have mainly as the result of private enterprise. Our success has been so far hampered by the well-meaning efforts of kind-hearted persons who have let their imaginations run away with them. This is not the place to discuss the question of vivisection; I am about to deal with it, elsewhere, and hope to be able to convince all but a few irremediables, that the Institute is entirely justifiable, and that sensitive and humane men may freely subscribe to it, as I again ask them to do. I must be allowed however to protest publicly against baseless charges of abominable cruelty levied against the medical profession as a body. I claim and I believe public opinion will support me that no profession is more full of sympathy for suffering or more prompt and eager to relieve it.

It is these same irremediables or others of a like kidney who, ignoring the alcoholic beam in the eye of England, wish to remove the opium mote from the eye of India regardless of the wishes and interests of her people. It is they too who prevent us from preventing preventible

disease, and thus make themselves individually instrumental in causing the conveyance of a horrible malady to numbers of innocent women and children, and in allowing the admissions from these diseases to rise from 15,006 in 1883 to 32,663 or 466 *per mille* per annum in 1893—figures which represent three regiments permanently in hospital and useless to the taxpayer. It is time that the common sense of mankind should refuse to be dictated to by a minority of imperfectly informed and unscientific persons whose zeal is in inverse ratio to their knowledge.

These then are the chief medical need; I now pass on to the sanitary needs of India, and I may begin by admitting that in spite of all that has been done, Indian sanitation, even in the large towns, is still in its infancy; while in many of the smaller towns it has not yet been born, and in most villages, not so much as thought of in a practical sense. Drainage, conservancy, water-supply, ventilation are all neglected; vaccination submitted to rather than welcomed, suggestions for improvement fall upon deaf ears, and there is neither the motive nor the money to carry them out. The solution of the problem seems hopeless, yet it must be found. The Governments of Europe are calling on India to attack cholera in its home. Practical sanitarians like Miss NIGHTINGALE suggest plans for doing so, exhortations, remonstrations, protests against the Government of India are not wanting, and it is lectured like a forward child for its shortcomings and supposed supineness. I tell you gentlemen as His Excellency the Viceroy has told us to-day, that the Government of India is willing and anxious to do what it can. It recognises, however, as all reflective people must recognise, the enormous difficulties in the way, not financial difficulties only, though these are many and great, but chiefly, and before all, difficulties due to the ignorance, prejudices, callousness and superstitions of the people. No Government, and least of all an alien Government, can ignore these. You can no more make people clean than you can make them moral by acts and regulations, and no laws or regulations are likely to be successful unless the educated opinion of the country is in their favor. People who have once learned the blessings and comforts of cleanliness even those below them. Each step in improved sanitation leads to others, progress widens slowly down from precedent to precedent, converts increase, knowledge spreads, and a sufficient public opinion is at last created to sanction and accept the reform. This process has had to be passed through in England, and has been an uphill task as all sanitarians can testify. In India the conservative habits of the people, the binding force of caste, of use and wont, of family traditions and the example of their fathers, make the work of educating them even harder still, while the general poverty of the country, as measured in coin, makes it very difficult to induce them to consent to measures which must involve fresh taxation. The results of Sanitary work are measured chiefly by vital statistics, but people have to be fairly educated before they can understand what statistics mean, and require the imaginative faculty to realize them when understood. A death-rate reduced from 50 to 20 is accepted with complacency, but even educated people have to think it over before they realize that in India such figures would mean the saving of 8,400,000 lives a year, and some 50,000,000

cases of avoidable illness. There are no such wasteries as sickness and death. Once get people to appreciate this, and they will be more ready to pay for preventive measures. At present they see that the cost is present and immediate, the results remote, uncertain and indirect. "All men think all men mortal but themselves," and the individual sees no reason why he should not live as long as another. In dealing with such opinions and prejudices the Government may well be cautious, but the idea once prevalent in Europe that it was also careless, is now, I hope, well exploded. The authorities know the evils and are willing to apply such remedies as may be possible. Putting aside, however, the difficulties already mentioned, supposing the people educated to the pitch of desiring the improvements which they now deprecate, we are at once brought up by the financial difficulty. Praise is constantly lavished on England on account of what she does for sanitation, and the praise is thoroughly deserved. But England is relatively a small country and enormously rich. India is, on the other hand, one of the largest, most populous and poorest of countries. The standard of comfort as measured in terms of European economics is low, though as the wants are few, it is really higher than it seems. The population of Great Britain and Ireland is under 38, that of India over 222 millions excluding nearly 67 millions in Native States. The revenue of England is in round numbers and excluding local items £91,000,000 in pounds sterling, that of India 64 millions in tens of rupees, and so terribly has that poor coin like Lucifer, fallen from his high estate, that, in spite of equalling or exceeding, as was the case 30 years ago, the pound sterling, ten rupees, is at present exchange only worth 11 shillings. The income of India is thus represented in sterling by £36,000,000. The revenue per head in England works out £2-8, in India three shillings and three pence or in the proportion of fourteen to one. Sanitary works also are probably more expensive in India than in England, for though labor is cheaper and engineering difficulties less, the trained staff is much more expensive, and much of the material has to be imported. It is said that England spends nine millions a year on sanitary works, and though I cannot find any definite authority for the statement, or any precise figures, this is probably an approximation to the truth. The expenditure has, moreover, been going on for years, and the great works already executed represent an enormous capital, the only direct interest of which is the improvement in the public health and consequent decrease of sickness and mortality. In India this capital has yet to be invested, and as her needs are greater, her expenditure should be greater than that of England. Do any of you realize what this means? It means an expenditure of nearly £53,000,000 a year to bring us to the English level—much more than the whole revenue of the country. It is clear, therefore, that even if the people were prepared for it, financial reasons alone make it impossible at present for the Government to deal adequately with general sanitary problems out of the public funds, or to "enforce sanitation," as they are airily requested to do by irresponsible sanitarians ignorant of the magnitude of their demand.

The tendency of opinion in India to look on Government as a sort of celestial Jack-in-the-box, ever ready to

spring to the rescue when affairs go wrong, is a very strong one, but the Government cannot work miracles or make two and two equal to five or three.

The people then are unwilling, the Government unable to provide means for efficient sanitation *per saltum*. Are we then to conclude that the problem is insoluble, a conundrum to be given up, and that we should sit down with folded hands and do nothing? I have many times heard the note of despair, I know that many men consider our efforts to be hopeless, and our views the dreams of visionaries, blind to facts and deaf to the voice of experience. I confess, gentlemen, that I take a more cheerful view than this, and while fully recognising the difficulties I have pointed out, refuse to impale myself on either horn of the dilemma. I hold that it becomes no man to brook despair, that by sitting still in face of a recognised evil instead of contending against it, we make ourselves responsible for it, and that it is only by "pegging away" that progress is possible. Our friends, the Fathers, will tell you that a "counsel of perfection" is the highest ideal of excellence, to be kept in view and striven for, although hardly to be attained by frail mortals. A model India with all the latest sanitary improvements is such an ideal. The man of little faith says, "it is high you cannot attain unto it." We can at least seek after it, and toiling hard against the stream of prejudice and difficulty see distant slopes of a sanitary Eden gleaming in the distance. As GEORGE HERBERT says—

Who aimeth at the sky

Shoots higher far than he that means a tree.

The map on the wall, the facts and figures that I have quoted to you shewing the progress that has been made, are to me full of significance and hope; and I now pass on to indicate the means by which in process of time our sanitary reformation is to be effected. There is much virtue in "the process of time" and if one thing is needful, it is time, you must hasten slowly, remembering that the habits and usages of centuries cannot be changed in a day, but can only be gradually modified by a slow progress of education. That progress is going on. The elements of hygiene are taught in primary schools, and no doubt produce impressions on some youthful minds. If the books which are somewhat dry and technical could be made more interesting, it would be a gain. Societies like the Calcutta Health Society, by tracts and lectures help the spread of knowledge, and I understand that my friend, Mr. HART, whom we are glad to welcome here to-day, has brought out a scheme for establishing branches of the Health Society of England in all important towns. Mockers will say—This is all talk, we want action. I have shown however, that action is impossible unless we carry the people with us, and much palaver is required to bring them on. As one of my counsels of perfection, I see a great hygiene service with a skilled Health Officer in every district, pointing out to a people anxious to follow his advice, their chief sanitary wants, controlling and inspecting vaccination, supervising water supply, conservancy, drainage, checking vital statistics, and regulating under the advice and direction of the Sanitary Commissioner the public health of the district. These multifarious functions are at present supposed to be performed

by the Civil Surgeon, who, in addition to his ordinary medical duties, is also responsible for the whole medico-legal work of the district, for the management as well as medical charge of the jail, and for the inspection of out-lying dispensaries. I know no more hard working and devoted body of men than Civil Surgeons. They accomplish the wonderful feat of serving not two but three or four masters, yet have not attained the accomplishment of SIR BOYLE ROGER'S bird, and cannot be in two places at once. The three main elements of successful sanitary and vaccination work are inspection and inspection and inspection. Without this it sinks into a sham which may make a fine show on paper, but will not bear stress or strain. A Civil Surgeon's inspections, as a rule, consist of a drive along a road to some branch dispensary, and then looking at what vaccinated children can be brought to him. He has no camp equipage permitting him to travel in the interior of his district, and if he had, the Collector would probably, and the Inspector-General of Jails certainly, object to his leaving the station for more than three or four days at a time. The necessity for special Health Officers then is plain. Where are they to come from, and how are they to be paid? I cannot shirk the problem, and must at least suggest some solution of it. The magnitude of the difficulties caused by the enormous size and population of the country have been pointed out, it is in the very magnitude of the population that I see grounds for hope. One anna, a trifle more than three farthings per head of the population paid to a special sanitary fund would produce in round numbers 14 millions of rupees, and would not only supply a Health Officer for every district in India, but would leave a very large balance available for sanitary works. When the people get to see the real value of sanitation, this anna and much more should be easily forthcoming, and the Health Officers themselves would be potent factors in the spread of sanitary enlightenment. The creation of health officerships would afford a career to many of our best graduates. Their pay would be provided by the sanitary fund, contributed by the people interested. Government would, in a general way, control and direct, deciding on questions of priority and so on, but the scheme would be worked mainly on local lines, by an amalgamation of village unions, contributing *pro rata* to a common fund. Self-help would have free scope and self-government be made more possible and real. To me it is a marvel that an educated community should cry to Government for everything as a baby cries to its mother. Sanitary improvements, the building and maintenance of hospitals are not in other countries paid for by Government. I have proved that the Government of India cannot supply them, though it does more for the medical needs of its people than any other Government I know. It is to municipal taxation levied for their individual and collective benefit by the people who pay it that we must mainly look, supported and enhanced by private benevolence. A good deal has already been given in this way, but it has been a mere drop in the ocean that is wanted. I commend the needs of the sick poor to all rich and charitable men, of whom there are many in India. I could dispose of many lakhs to great advantage if they were placed at my disposal. We want ten for a new Medical College alone, and

I am sure His Excellency would be greatly obliged if any one would save him from the difficult task of finding it from the State coffers.

Such, gentlemen, are the sanitary needs of India, the aspirations of her sanitarians. If I have seemed to give to airy nothings a local habitation which has as yet no objective existence, I can only repeat my belief that time will turn them to shape, and that, by slow degrees no doubt, but still advancing, the progress of the last few years will continue and increase. I would ask all the members of this Congress to be of good courage. Everyone of us can do something to promote improvement; and we should never relax our efforts in the fight against darkness and ignorance, and all the suffering which they bring. Beaten we may be for a time, but let us—

Combating because we ought to combat
Rejoicing fight, and still rejoicing fall

Sure that victory will come, if not to us to our successors.

—:0:—

THE FEVERS OF INDIA.

By SURGN. LIEUT.-COL. ALEXANDER CROMBIE, M.D., I. M. S.

*Being the address of the President of the Section
of Medicine and Pathology of the Indian
Medical Congress.*

GENTLEMEN,—While I acknowledge the great compliment which was paid to me by my nomination to the distinguished position of President of the important section of Medicine and Pathology at this the first Medical Congress held in this country, I trust you will accept, not as merely formal and customary, but as genuine and heartfelt, my expression of regret that some one has not been selected who might have filled the place I now occupy with more learning, grace and ability, than I can hope to bring to your service. In order to minimise as far as in me lies the disqualifications under which I take my place here, I have selected for my presidential address a subject which has an instant and perennial and daily interest for all of us who practise medicine in India, and one to which I have given much thought throughout my whole service, and the importance of which no one will be disposed to dispute. It is now nearly twenty years since I was requested, among other officers serving in Burma at that time, to report on the fevers of that country, and from that time, till now, my mind has never been long unoccupied with the great, important and complex problem which Indian fevers present. To the European living in Europe, on account of the almost theatrical rapidity of its course, its high rate of mortality, and the mysterious way in which it seems periodically to escape from the limits of the endemic area, and carry devastation westwards in a progress which neither rivers, nor seas, nor quarantine are able to stop, cholera looms large in the catalogue of Indian diseases. But we who live and practice in India know that in many parts, cholera, as in Europe, is only an occasional visitor, and that even in the endemic areas, where though it has its seasons, it is never wholly absent, and while it demands its victims in hundreds, fever exacts

them in thousands. The number of deaths due to cholera in the whole of India in 1892 was recorded roughly as 750,000, whereas the number of deaths attributed to fevers was, also roughly, 4,500,000. Now if we remember that the death-rate in fevers is probably highly estimated if we place it at two per cent., while the death-rate in cholera is not much below 50 per cent. of the cases, we at once perceive what an enormous amount of sickness, suffering, and disability is comprehended in the words Indian fevers, and what an enormous amount of clinical material there is presented to us yearly for their study. The above figures, worked out, give us somewhere about 200,000,000 cases of fever per annum against 1,500,000 cases of cholera. The pre-eminent importance of fevers in the daily life of an Indian practitioner can, therefore, hardly be disputed, and I need I think make no excuse for selecting them as the subject of my address.

The fevers of India divide themselves into two great classes or groups:—In the first of these are those fevers whose course is interrupted by more or less perfect periods of apyrexia, and are, roughly speaking, amenable to treatment by quinine. These are the malarial fevers, and in the second group are the continued fevers, in which quinine is of no avail. With regard to the first, our knowledge is precise and almost complete; with regard to the second it is still hazy and to a large extent conjectural, and yet it is in this second group that are found the fevers, the fatal character of which, goes so far to swell the death-rate of India to its huge proportions.

I will speak first of the fevers in which periodicity is the distinguishing character, namely, the malarial fevers. It is customary to sub-divide these into intermittent and remittent fevers. With regard to *intermittent* fevers we are all of one mind, and there is no question, and can be no question, as to their position, but of late years there has arisen a good deal of doubt, first, as to whether there is any fever which can be called remittent, and if so, whether it should be included among malarial fevers. I confess to placing myself among the sceptics for reasons which will presently appear.

Beginning then with those fevers which in their normal or typical manifestations have distinct periods of perfect apyrexia, namely, the intermittent fevers, I would point out in the first place that they do not in India follow the same order of frequency as they do in other countries. In those parts of India in which I have had opportunities of observation, *quotidian* ague takes the first place in order of frequency. At most seasons I would not probably be wrong in saying that 90 per cent. of the cases of ague we have to treat have daily paroxysms of fever and not more than 10 per cent. are *tertian* in type, while *quartan* ague is so rare that it may be practically left out of account. I have only had to treat one case of quartan ague in the whole of my twenty-two years' service in India, though I heard of another case a few weeks ago, but was unable to see it. In other malarial countries the order of frequency is quite different. In the Roman Campagna, for instance, the majority of the cases are *tertian*, then come *quartan*, and last of all the *quotidian* ague. To this fact, the comparative infrequency of *tertian* and *quartan* ague, I attribute the reluctance which is still shown in some

quarters in India to accept the amoeba of LAVERAN as the true pathological cause of the symptoms of malarial fever, because in quotidian ague, the amoeba is often difficult to find, for the reason of its small size, its often indistinct form, and because it does not go through all the phases of its cyclical life in the blood of the general circulation. In tertian, and specially in quartan ague it is of large size, well pigmented, and generally requires no great research to find it, and in quartan ague its whole life history can be followed in blood taken at intervals from the finger. To study the most critical part of the cyclical life of the parasite in tertian and quotidian ague, namely, the periods of segmentation and sporulation, blood must be taken from the internal organs. From these remarks you will guess, and I may as well at once confess, that I am a convert to the amebic theory of malarial fever. It seems to me that it is impossible to offer any longer a reasonable resistance to this theory. Malarial fever is found to exist in widely different parts of the world, in America, Africa, Asia, and Europe, and in localities differing from each other in every particular of climate. Yet under all these varying conditions the phenomena of malarial fever are identical, and point to an identical pathological cause. In all these places, an examination of the blood of patients exhibiting these symptoms discloses the presence of a living organism which is the same in each place, the same in Africa and America as in Bombay and Calcutta; furthermore, the cyclical growth and development of the parasite is found to correspond with the cyclical periodicity of the fever, the apyrexia corresponding with the appearance of the young amoebae in the corpuscles and the accession of fever with their sporulation and the discharge of their presumed toxin into the blood. If it is to LAVERAN we owe the discovery of the relation of the amoeba to malarial fever, it is to Italian physicians, and especially to GOLGI, MARCHIAFAVA and BIGNAMI, that we owe the working out of its life history, and it seems to me impossible to resist their conclusions.

GOLGI has made quartan ague his special study, and the case with which the life of the amoeba of that form of ague can be studied in the blood of the finger, makes it very enticing. Its cycle of life is shortly as follows, and I am glad to have this opportunity of saying that I was able, even with my very imperfect observations, here in Calcutta, to confirm those of GOLGI and MARCHIAFAVA, as far as I could do so in the single case of quartan ague, which came under my observation last year. In the first day of the apyrexia the amoeba will be found, perhaps, two or even three in a single field of the microscope as in my case, occupying about $\frac{1}{4}$ or $\frac{1}{2}$ of the invaded red blood corpuscles and exhibiting active amebic movements. On the second day of apyrexia, it will be found that it has grown so as to occupy half of the blood corpuscle, to have become pigmented at the periphery and to have all but lost its motility. On the third day of apyrexia it will be found to occupy nearly the whole of the corpuscle, and that the pigment has collected towards the centre preparatory to segmentation. The next and last stage of the cycle of life is that of sporulation, and with the discharge of the spores, and of the toxin which the amoeba is supposed to form, comes the sudden accession

of fever on the fourth day. When this happens over and over again, the same relationship being repeated between the growth and maturation of the amoeba and the periods of apyrexia and pyrexia in the patient, it becomes irresistibly borne in on one that they bear an intimate and indeed casual relationship to each other.

The study is more difficult in tertian, and most difficult in quotidian ague, because the amoebae of these forms of ague cannot always be found in the blood of the finger, retiring as they do to the spleen, brain, and bone marrow to undergo their final stages of segmentation and sporulation prior to a renewed accession of fever, and indeed it is sometimes only on *post mortem* examination that the important part they have played in the phenomena can be understood, the number of amoebae in the general circulation not being always proportionate to the severity of the symptoms. All that is wanted to satisfy the most exacting demand for complete evidence that the amoeba of LAVERAN is the very cause of intermittent fever is, that it should be cultivated outside the body in some suitable medium, and that when a pure culture so obtained is injected into the body of an animal susceptible to the disease, it should give rise to the symptoms and pathological changes of intermittent fever. Hitherto the amoebae of malarial fever have baffled every attempt of this kind if it be not true as was reported a few months ago that CELLI of Rome has succeeded in growing them in some alkaline medium.

It would require a much more prolonged and continuous study than it has been in my power to give to this subject, before I could say or ask you to believe, with MARCHIAFAVA, that each form of malarial fever has its own variety of the parasite, and that you can tell, by its microscopic characters which variety is present and that the specimen of blood is taken from the finger of a patient suffering from quotidian, tertian or quartan ague as the case may be; but it is my firm belief that there is little difficulty in doing so, and my own observations here in Calcutta, as far as they go, go entirely to confirm the observations of the great Italian observers as may be gathered from the phrases I have used in speaking of the parasites of the different forms of intermittent fever, as if they were distinct. I have now seen every form of the amoeba, both the endoglobular and the ectoglobular bodies belonging to the semilunar group with the exception of the flagellate forms in patients in the General Hospital in Calcutta, and they exactly correspond with what I saw in Rome, and is described and pictured in MARCHIAFAVA and BIGNAMI'S book; not only so, but the variety described as that of quartan ague was found existing alone in my case of quartan ague I have alluded to. Here the commonest variety is the annular form found in our cases of quotidian ague exactly like that found in cases of quotidian ague from the Roman Campagna, and the same correspondence will be found also, I believe, in the tertian ague of the two countries.

I now pass to those cases of malarial fever in which there is no distinct intermission. These form an important proportion of the cases of fever treated under the name of remittent fever, and allow me to say, at once that we all recognise two kinds of remittent fever, a malarial

and a non-malarial, which latter I however regarded as a continued fever; and will consider later as one of the group of continued fevers. But at a certain season of the year, that is from the middle of September to the end of December in Lower Bengal at least, a very large percentage of cases of remittent fever partake of a different character, that is to say, they are clearly of a malarial nature, and are equally with the varieties of intermittent fever mentioned before, amenable to treatment with quinine. There is little room for doubt that this group of fevers the malarial remittents as also produced by the same amoeba forms, as produce the intermittent fevers, and that they are in fact intermittent fevers in which either the pyrexial stage is unduly prolonged, owing to the excessive toxic qualities of the organism, so that a new accession of fever comes on before the previous attack has entirely subsided, giving time only for a small remission of the pyrexia previous to the next accession, or they are cases in which there are at one and the same time two sets of organisms in the blood whose cycles of life are parallel, but not synchronous, one maturing, sporulating, and discharging its toxin some eight, ten or twelve hours after the other, and thus keeping up a continuous condition of pyrexia. Just as there is a double tertian, so there may be, and in certain of the cases I refer to there is a double quotidian producing the phenomena, which constitute what is described as malarial remittent fever. I have not made a sufficient number of observations to verify those of MANCHIAFAVA who has found corroboration of this theory of malarial remittent fever in the existence of amoebæ in different stages of cyclical growth in the same drop of blood, but I have found the annular forms of the amoeba present in cases of remittent fever in no way to be distinguished from those so constantly found in the quotidian form of intermittent. I confess, however, that these are most trying cases to investigate microscopically, at least in the time usually at my disposal for these purposes; and I have in most cases been obliged to form my diagnosis on general clinical symptoms.

We must, therefore, in many cases fall back on general symptoms in differentiating the malarial from the non-malarial form of remittent fever, and the clinical features on which we must depend to justify the diagnosis of an element essentially malarial in these cases are the following:—(a) the history of a distinctly intermittent character of the symptoms at an earlier stage before they become remittent in type,—(b) the existence of a more or less distinct remission of the pyrexia at a fairly regular time of the day or night or (c) the occurrence of two remissions, however slight, and two exacerbations in each period of twenty-four hours suggesting the existence of two sets of organisms maturing separately. Observations of this nature require the most intelligent care and record, but when one or other or all of these phenomena are present you know that you are dealing with a case of malarial poisoning, and you must exhibit the antidote even though no malarial organisms can be found in the blood of the finger.

One more word before I pass to the consideration of the group of continued fevers. It may be asked, what practi-

cal good is obtained by the discovery of the malarial parasite in the blood. The clinical phenomena are already sufficiently clear to enable us in nine cases out of ten to dispense with the microscope in forming our diagnosis. This is no doubt true, but not to mention the aid to prognosis afforded by the number of parasites present and their effect on the red corpuscles which they have invaded, there are cases in which the diagnosis is not quite easy, and in which the discovery of the parasite would free the mind of the physician from doubt and perhaps anxiety, and enable him to use the antidote with a freedom and confidence which he could not otherwise feel. Thus in my own practice last year I had a case of urinary infiltration which, while apparently doing well, was suddenly seized with rigors and a rapid rise of temperature followed by profuse sweating, symptoms which under the circumstances were uncomfortably suggestive of pyæmia. An examination of the blood shewed the presence of the amoeba of tertian ague, and led to the administration of a few full doses of quinine, and the cessation of all the symptoms. I venture to think that without the microscope the treatment would not have been so assured or so prompt and effective. In the puerperal state similar assistance would often be of the greatest comfort to us. It is only fair in me to say, however, that in many cases the observer must be prepared for disappointment. The examination must often be prolonged and repeated, and there are various fallacies lying in wait for the inexperienced and in certain instances where the general symptoms, and the prompt response to the action of quinine leave no ground for doubt as to the malarial character of the case; the most patient search sometimes fails to find any organism in the blood of the finger. In such cases the blood of the spleen would probably yield them abundantly. While, therefore, the presence of the malarial parasite in the blood of the finger may be regarded as conclusive of the malarial nature of the case, failure to find it can in no way justify the opposite conclusion in the face of distinct clinical symptoms of a malarial type.

And here pardon me one moment, that I may speak of the efficient use of quinine. There are many practitioners in this country who from timidity or wrong teaching or some other cause, have no knowledge of, and I fear also no belief in, the power of quinine as an antidote for malarial poisoning. How, when or where, the practice originated I cannot discover, but the belief is widespread, among professional men, as well as among the laity, that quinine cannot be safely or efficiently administered except during the period of apyrexia or at least in remittent fever its administration must be delayed till a remission has occurred, such as to bring the temperature down to some point below 100° Fah. All the best authorities advocate a very opposite plan of treatment, and I am glad to have this public opportunity of recording an emphatic dissent from the popular belief and practice. Careful observations have shown that quinine is most efficient against the malarial organism in the early period of its growth, while it is still unpigmented or only collecting pigment at its periphery, i.e., in quotidian ague during the pyrexia and the crisis. When the amoeba ceases to grow and begins to prepare for segmentation and sporulation that is, just before the rigor and new accession of fever, quinine has little or no effect on it, and I entirely agree with MANCHIA-

FAVA and BIGXAMI, that in malarial remittent, where there may be, and frequently are, two sets of organisms maturing separately and severally, at different times, in the blood, the treatment with quinine should be begun without delay and continued at regular intervals without any regard to the state of the temperature curve. My own practice is to give ten or fifteen grains by the mouth, every four or six hours, according to the severity of the symptoms.

I have never given more than 90 grains in 24 hours, and I usually find one drachm in 25 hours serves my purpose, but in the hospitals of Rome, where they encounter a type of fever of a severity such as we rarely meet with here, and which may prove fatal by coma in 48 hours, physicians administer much larger doses. Their initial dose is seldom less than thirty grains, in two doses, at an interval of two or four hours, and pernicious cases they give hypodermic injections of 30 to 45 grains, followed by smaller doses of 15 grains.

If when the time of my leaving India comes I were to leave a message to my professional brethren here, it would be this,—treat your cases of malarial remittent with quinine, early in full doses with a free and fearless hand and regardless of the temperature.

Gentlemen, I yield to no one in my advocacy of the freest use of quinine in malaria, but at the same time I deprecate and deplore that indiscriminate use of it in unsuitable cases, which has brought this invaluable drug into so great disrepute among the natives of this country, and has given rise to a dread of it, both on the part of patient and practitioner, which effectually prevents its effective employment in cases where it is the only hope of salvation. In this instance, as in every other, a careful diagnosis is essential. If after a painstaking enquiry the case appears to be one of the second group of which I am about to speak, the group of continued fevers, withhold quinine or give it sparingly and tentatively, but if you come to the conclusion that the case is malarial, you cannot give it too freely or fearlessly or with too lavish a hand.

I now come to the second group of fevers, our knowledge of which with perhaps one exception is unfortunately still vague and conjectural, and in which quinine is not only of no avail, but is sometimes distinctly harmful. I refer to the continued fevers of which I recognise with certainty three, and probably five as specifically distinct. The three whose differentiation I regard as indisputable are *simple continued fever*, *typhoid fever*, and *non-malarial remittent*, so called,—the other two whose title to a distinctive name you may be disposed to doubt are a fever especially of towns known locally as "*Calcutta fever*," "*Bombay fever*," etc., which runs a course very similar to that of typhoid fever without any of the symptoms of that disease, and lastly there is a low continued elevation of temperature of indefinite duration and without any distinctive symptomatic features, and known simply as "*low fever*."

I do not propose to allude to ephemeral fever, of 24 hours duration and due to chill or slight exposure to the sun, or to that extremely sudden severe and fatal form of fever called *insolation* or *sun-stroke*, or the cerebro-spinal or typhus fevers, but I would venture to remark that whatever the returns of the armies, both European and Native and of civil hospitals and jails, may seem to say to the contrary,

the most common fever of India is not *ague*. The fact that "*ague*" takes the first place in the returns is merely due to a looseness of nomenclature which leads medical officers, at the instance generally of their subordinates to return as "*ague*" every case of fever of short duration, as well as those which show the intermittent character which entitles them to that name. I was a very short time in India before I began a fight on this subject—a battle which continues even unto this day. To my mind no fever is entitled to be called *ague* which does not conform to a certain type, that is to say, unless its course is interrupted by intervals or more or less complete apyrexia.

Now in the parts of India where my lines have fallen a type of fever with this essential character has at no time or place been the prevailing one as the returns referred to would lead one to suppose, and if you were to refuse to accept as *ague* all cases of fever except those in which intermission was an essential feature, you would sweep away at once some three-fourths of the cases now returned under that name. In certain months of the year, that is to say in October, November, and December, true *agues* are more frequent than at other seasons, but even then they by no means constitute the majority of the cases, and for nine months of the year it is often difficult even in a large hospital to find a case of genuine *ague* for weeks at a time.

The cases which are thus wrongly returned under the heading of "*ague*" are really cases of "*simple continued fever*," a fever often ushered in with a rigor, a very high temperature and evidence of great gastric disturbance. I have known the temperature reach 106° Fah, within a few hours of the commencement of the symptoms, but more usually the ingress is more gradual, though the headache and gastric symptoms are generally very distressing. The duration of the case is generally from three to eight days, and there is often much doubt whether it will or will not pass into typhoid when the patient is a European, and especially if he is living in a drained town.

Such cases are examples of a distinct type of fever which has been recognised and described by all the best authorities under the name of simple continued fever, a name to which there is no objection. But instead of determining within a week it is not very unusual, especially during the cold season, and early summer for these cases to continue for a longer time, and then we look for deferrescence about the 14th, 21st or 28th day. These cases are particularly common in towns and are known as "*Calcutta fever*" "*Bombay fever*," etc. It is open to any one to assert that these are cases of mild typhoid fever, and that those which recover early are merely abortive cases of that disease. It is, however, I think impossible for one accustomed to treat considerable numbers of cases of true typhoid fever, and who also has opportunities of watching the imperceptible gradation of cases of simple continued fever into the cases now under consideration, not to notice distinct differences which forbid him to concede more than that certain mild and abortive cases of typhoid may be mistaken for cases of the continued fever of our towns. I am one of those who are unable to admit that the whole philosophy of continued fever in India can be epitomised in the word typhoid. I cannot admit that the bacillus of ESCHERICH is the only organism capable

of giving rise to a febrile curve of three or four weeks' duration. As a matter of fact, it is known and has been experimentally proved in animals that a bacillus normally present in large number in the human intestine, the bacillus coli communis, is capable under certain conditions of becoming virulent and then endowed with a power of producing a fever and even pathological appearances, including ulceration of the bowel, hardly to be distinguished from those of typhoid fever. It has always, therefore, seemed to me to be narrow and unjustifiable to classify as necessarily typhoid every case of continued fever of three or four weeks' duration. If the bacillus coli communis is sometimes endowed with this power, why not also some other organism or organisms as yet unknown? With the knowledge of this possibility before my eyes, I have been accustomed to insist on the presence of certain symptoms resembling those of typhoid fever before being prepared to concede that any given case of continued fever is one of that disease. Now such symptoms in the cases I refer to are conspicuous by their absence. It is true that genuine cases of typhoid fever, often in this country, present remarkable variations from what may be considered as typical of the disease described in text-books. I need only allude to the frequent absence of that gradual step like rise of temperature during the first three or four days which is so characteristic of typhoid fever in Europe. Instead of that we quite frequently, and I believe it to be the rule here, have a sudden rise to 104° on the first and subsequent days. I need not mention the alleged more frequent absence of the characteristic eruption here, because I do not think it is more often absent here than in Europe, and even if it were it is not so much the absence of spots which constitutes our difficulty of diagnosing typhoid in India, but rather the superabundance of spots, at least in the hot weather and rains, when the whole body is covered with prickly heat, in the exuberance of which it is as hopeless to pick out typhoid spots as to find the proverbial needle in a bundle of hay. Neither do I speak of the difficulty of seeing the spots on pigmented skins, because as I have pointed out elsewhere, the native races of India exhibit a marked immunity from typhoid fever, with the exception of the lighter coloured races, the Gurkhas and Burmans, and perhaps other meat-eating and drink-drinking people. Neither do I speak of the relative frequency of constipation in typhoid fever in India, because I do not think it is more common than in Europe; and because I believe that the constipated motion of a genuine case of typhoid with its appearance of orpiment paint is as characteristic of the disease as is the pea-soup stools of typhoid diarrhoea. But what I maintain is that we are not justified in designating as typhoid fever cases which have neither the gradual initial rise nor the eruption, nor the characteristic stools, whether loose and like pea soup, or constipated and like yellow coach paint, cases in which the tongue continues clean and moist or simply coated as in any febrile condition, and in which the mind is clear throughout unless you give quinine. I say we are not justified in calling such cases, in which all the symptoms of typhoid fever are absent, enteric fever, simply because they have a duration of three or four weeks. I

demand that some one or more of the ordinary symptoms of typhoid fever should also be present. Neither will I admit that even hæmorrhage from the bowel necessarily removes them to that category if it be true that other febrile infections besides that of typhoid may also give rise to intestinal ulceration. I believe that these cases, which I am now describing, and which are so sharply differentiated from typhoid fever by the whole clinical picture which they present constitute a specific disease, and must have a specific and separate cause distinct from the bacillus of ENTERIC.

A very few words will suffice to dispose of the next form of continued fever. It is one which is only occasionally met with among Europeans, and I do not think I have met with it in natives in India, but if it does occur among them it would hardly be brought under my notice. I refer to a persistent low elevation of temperature unaccompanied by any constant symptoms, of indefinite duration, and uninfluenced either by quinine or arsenic. The temperature never falls below 99° and rarely rises above 101.5. It may continue for several weeks without complication except, perhaps, a tendency to diarrhoea of a bilious character, with loss of appetite, and gradual loss of strength and flesh. Some of these cases are distinctly aggravated by quinine, and I have known them cease abruptly on withdrawing the drug which had been persistently given in the belief that the condition was malarial in its essential nature. These cases are spoken of as "*low fever*" and are generally cured by a "change" of any kind, but especially by a trip to sea, and it is especially this form of fever which in Calcutta is benefited by a visit to the Sandheads. Though very ill-defined, these cases constitute a distinct type of fever at once recognised when met with.

Widely different from this "*low fever*" is the last form of continued fever of which I have to speak, namely, the *non-malarial remittent* (so-called). It is a pity we have no better name for this fever, which is of very frequent occurrence, and is one of the most fatal of our fevers. The designation "*remittent*" is a misnomer. It is no more remittent, and indeed often less so than typhoid. The temperature is generally very high, touching 104° and 105° for a long part of its course, and the daily fluctuation not exceeding 2° or 2.5°. It begins in a way not unlike the cases I have described under the name of "*Calcutta fever*," "*Bombay fever*," etc., and is by some considered to be a variety of typhoid fever, not withstanding its divergence from all the symptoms of that disease. Hepatic enlargement and congestion are early and constant conditions; but the spleen, as a rule, continues impalpable below the ribs. Bilious diarrhoea, in no respect resembling the diarrhoea of typhoid, is also a very frequent symptom,—quinine often given in large and repeated doses in these cases is not only not useful but so obviously adds to the distress of the patient without in any way producing an improvement in the progress of the symptoms that it is very soon abandoned. Meanwhile the temperature continuing persistently high marked head-symptoms, especially delirium of a muttering and irritable kind, comes on, and the patient may even and often does pass into a condition of coma from which he can hardly be roused. This condition, one of persistent high temperature without any

marked remission, a distinctly enlarged and congested liver with bilious diarrhoea, congestion of the back of both lungs, and a low muttering delirium is generally reached by the 10th to the 24th day. If coma supervenes, the patient frequently dies about this period. In more favorable cases where the symptoms are less severe they continue for a week or two more, and the average duration of the case is six weeks. None of our drugs seem to be of any use in shortening it, certainly not quinine, the inadequacy of which in these cases has now become fully recognised, though the disease has not yet found a name or place in our nomenclature.

Though I have seen this fever in Europeans, it is essentially a disease of Natives, and is not common after thirty years of age, though frequent enough in childhood. Like every other continued fever in India, this also has been called typhoid fever, though it is difficult to conceive a condition more distinct from it in its symptoms or course. This is the fever which offers the highest promise to the enquirer of the near future. It is obviously not a malarial fever, and no unprejudiced observer would for a moment class it with typhoid, and yet it has such a perfect and constant clinical course that it must have a special and specific cause, some organism which is waiting its discoverer. Such a discovery has at last been made with regard to "Malta Fever," a fever long and persistently considered to be typhoid, but now proved by the researches and experiments of BRUCE, GIPPS, and HUGHES of the Army Medical Department to be as distinct clinically, pathologically, and bacteriologically from typhoid fever on the one hand as it is from malarial fever on the other. It has been my fortune to watch some twenty cases of Malta fever in the General Hospital, and it is difficult to understand how it could ever have been regarded as related, even to typhoid fever, so different is it in its clinical character alone. The gentlemen I have named have succeeded in isolating the organism which is its essential cause, and have been able in six instances to induce an analogous fever in monkeys by means of pure cultivations of the "micrococcus melitensis" as it is called. Malta fever has no congener in India, but should not the success of BRUCE, GIPPS and HUGHES stir us up to a scientific investigation of our Indian continued fevers? These investigations are not really difficult. Their essential requisites are a few simple stains and a patient looking through the tube of a microscope. We have allowed a Frenchman to find in this way for us the amoebae of our malarial fevers and a German the comma-bacillus of cholera, which is surely our own disease. Shall we wait till some one comes to discover for us the secrets of the continued fevers which are our daily study, or shall we be up, and do it for ourselves? It may be that I have wearied you with my address, the subject of which is necessarily one of technical detail. It may be that you differ from me entirely in my opinion as to the nature of the fever which I have now attempted however feebly and imperfectly to differentiate and classify, but if I have succeeded in rousing any of my hearers or any of those who may do me the honor of reading my remarks to a more careful clinical study of the cases which come

daily under our observation in this enormous field for clinical study, in which we work, and there must be many better qualified for the task than I am; and especially if I can hope to rouse in those who have more leisure than I, the determination to study these fevers bacteriologically and to make a precise knowledge of their true nature our own, I shall be content and think that I have perhaps not written and spoken in vain.

—:—

THE INFLUENCE OF PERCIVAL POTT, SYME, SIMPSON AND LISTER ON MODERN SURGERY.

By SURGN. LIEUT.-COL. EDWARD LAWRIE, M.B., M.R.C.S.

*Being the Address of the President of the Section of
Surgery of the Indian Medical Congress.*

GENTLEMEN,—I feel the distinction of being selected to fill the important post of President of the Surgical Section of the Congress as the very highest honor that could have been conferred upon me. At the same time I may say without affectation, that I am almost overpowered by the sense of my unfitness to fill that position, and fear lest I may disappoint many of you in the remarks I am about to make.

In surgery I am strongly *conservative*, and there are many men in our service in India who have far higher claims to be considered scientific surgeons, and who would have done far greater justice to the developments of modern surgery than I can do.

On the other hand, I am convinced that the experience you will bring to bear upon the many important surgical questions which will come before the Congress will have lasting consequences in the future, and will much more than atone for the shortcomings on my own part to which I have referred.

The only thing I can say in my own favor is that I am a staunch admirer of British surgery, and especially of British surgery in India. I find it impossible to overestimate the value of what I learnt in general surgery, and also about chloroform, from PARTRIDGE, who was the Professor of Surgery in the Medical College here when I first came to India.

I have never seen more perfect operations for dataract than those of J. B. SCRIVEN, of Lahore, nor sounder and more brilliant abdominal operations—not even excepting those of KNOWSLEY THORNTON—than those of BRANFOT of Madras. Further, I venture to assert that the Surgery which has been done in the North-West of India during the last 20 years by FREYER, SANDERS, KERRAN, GEOFFREY HALL, WILLCOCKS, PERRY, the NAYES in Cashmere, and a host of others, as well as by the men they have taught, has done and is doing more to establish kindly and friendly relations between the natives of England and the natives of India, than any of the numerous beneficent enterprises which have been fostered by Government for the benefit of the people and the country since India became part of the empire of the Queen. Finally, I may relax, with I hope, pardonable pride, and which I trust will be shared by the Government of His Highness the Nizam, a piece of surgery which has just been done by one of my own pupils.

This youth, till lately an Assistant House-Surgeon at the Hyderabad Head-Quarters Hospital, performed a Listerian ovariotomy successfully, at a lonely out-station in the district, with no other assistance than that of a compounder and two coolies. One of the coolies gave chloroform, the other looked after the instruments, sponges, lotions, dressings, and the friggerator; and the compounder acted as first and second assistant combined.

Gentlemen,—I have thought long and anxiously over the problem of the best way of occupying the time at my disposal for the delivery of the formal address on surgery before this the first Indian Medical Congress. The conclusion I came to was that we cannot do better than consider the influence of four great British surgeons on Modern Surgery,—PERCIVAL POTT, SYME, SIMPSON and LISTER. I have chosen these names from among the numerous great names there are to select from, for many reasons, one being that they are the four whose lives, writings, and example I know best: and further because they are Englishmen, and no other country that I know of has produced four men who have accomplished so much as they have for surgery. PERCIVAL POTT represents the surgery of the latter half of the eighteenth century. He resigned the office of Surgeon to St. Bartholomew's Hospital in 1787. SYME and SIMPSON resigned their posts of professors of Clinical Surgery and of Midwifery respectively in the University of Edinburgh nearly a hundred years later. POTT and SYME both served their schools, as POTT used to say of himself, "man and boy" half a century. In one of his well-known tracts POTT says:—"Our fathers thought themselves a great deal nearer perfection than we have found them to be; and I am much mistaken if our successors do not, in more ways than one, wonder both at our inattention and our ignorance." We must admire POTT's modesty; but when we think of the work accomplished by him, by SYME and by SIMPSON, we cannot help wondering at their genius, their skill, and at the imperishable principles of surgery they have handed down to us and to our successors. The last of the four, SIR JOSEPH LISTER, is still with us, and we all know that his work constitutes the subject we are about to consider chiefly to-day, namely Modern Surgery.

Up to the time of POTT the state of surgery was imperfect. Operations were unnecessarily painful. The maxim, "*dolor medicina doloris*," was accepted as fully demonstrated. Dressings were painful, the actual cautery was prepared as a part of the necessary apparatus when the surgeon paid his daily visit to the hospital; and the natural processes of healing were either not recognised or disregarded. POTT's biographer states that he lived to see these remains of barbarism set aside, and a more rational plan, of which he was the chief author, universally adopted. POTT did not commence to write until the year 1756, when he was over forty years of age, and had acquired a vast amount of experience in surgery. Between that time and the year 1787 his writings were numerous, and many surgical conditions which he was the first to describe, such as fracture of the fibula with dislocation of the foot, and angular curvature of the spine, will always be known by his name. He wrote what he called

"tracts" on many diseases in surgery, and not only accurately described them for the first time, but also laid down principles for their treatment which hold good to the present day. There is unfortunately not time to do more than enumerate the subjects on which he wrote, and is still an authority, such for example as curvature of the spine, hernia, polypus of the nose, cataract, hydrocele, injuries of the head, fractures and dislocations, compound fracture, diseases of the rectum, chimney sweep's cancer, aneurism, gangrene, amputation, and so forth. POTT was singularly successful with the trephine, and his essay on injuries of the head is well worth careful study in connection with recent advances in brain surgery, for which we are so much indebted to the splendid work of FESSLEMAN and VICTOR HORSLEY. POTT discovered that when the bone inflames after a blow on the head, and a puffy inflammatory swelling makes its appearance in the scalp covering it, this generally indicates suppuration exactly opposite the same spot, on the inside of the cranium, which may be relieved by laying on the trephine. POTT published a most interesting and remarkable series of cases of head injury, numbers of which were lost from simple inflammation and pressure, or from sepsis. There is very little doubt that most, if not all, of the cases to which I refer would have recovered if he had known the secrets of antiseptic surgery, which we shall see later he very nearly stumbled on to accidentally, and the modern use of antimony in the prevention of simple inflammatory conditions. When inflammation of the contents of the skull threatened to arise after injury of the head, POTT's only available remedies consisted mainly of phlebotomy and the trephine, and he certainly used them most freely. Where he employed phlebotomy and the trephine in cases of threatened intra-cranial inflammation, we now use antimony, either in good big doses at long intervals or in small doses frequently repeated, and if it is a simple uncomplicated inflammation, the antimony very often cuts it short and saves the patient's life and obviates the necessity for an operation.

Before POTT's time *Fistula in ano* was treated on a principle advocated by CHESLETON, by first dilating the sinus with sponge tents, then one of the blades of a large pair of forceps was to be thrust up the sinus, so that it and the other within the intestine pinched it between them. The piece so pinched was next to be snipped out by repeated attacks with a knife or a pair of scissors. As POTT says:—"A very tedious and painful operation this must necessarily be, and by Mr. CHESLETON's account not always successful." POTT rescued the operation for fistula from the domain of undue severity and uncertainty, and placed it on the footing it occupies to this day. He says:—"The curved probe-pointed knife, with a narrow blade, I have always found to be the most useful and handy instrument of any. This introduced into the sinus, while the surgeon's forefinger is in the intestine, will enable him to divide all that can ever need division. The probe point of the knife will be received by the finger in ano, and will thereby be prevented from deviating, and, being brought out by the same finger, must necessarily divide all that is between the edge of the knife and the verge of the anus, and lay the two cavities of the fistula and of the intestine into one."

In the same way with the operation for *Internal Hemorrhoids* POTT shewed that the proper principle to employ in removing an internal pile, is to ligature it just below the middle, and not at its base, or by pulling it bodily with part of the mucous membrane from which it grows, through the noose and then tying it. If you look at the diagram, you will see that the wound left by the separation of the ligature in POTT's plan, is no larger than the knot, and as it never gapes, it heals up in a few days after the ligature comes away on the fourth or fifth morning; whereas it is also plain that the wound, when the base of the pile, or worse still when mucous membrane is included in the ligature, is necessarily a gaping one, and may take months to cicatrize. As in the case of fistula the principle of POTT's operation for piles holds good at the present time, whether the ligature, or the clump, or crushing, or any form whatsoever of excision, be employed for their removal.

It must not be imagined that piles and fistula are diseases of too trivial a nature to demand our serious notice. They cause an immense amount of misery and suffering in the world, which can only be properly alleviated by treatment founded on correct principles. It is well to remind ourselves occasionally of correct principles: for a very few months ago, there was a proposal in the *Lancet* to revive CHESLENDEN's operation of excision for fistula, and only last year a gentleman of my acquaintance came out from England, who was compelled to undergo treatment for four months after he landed in India, while an indurated wound in the rectum, due to the removal of too much tissue in an operation for internal piles, was healing up.

I much regret that time will only permit me to draw your attention to one more subject in surgery on which POTT left the record and stamp of his genius. I allude to *fractures*, and it is curious to note that almost every word he wrote on the principles of their treatment, more than a hundred years ago, is true to-day. He begins his tract on fractures and dislocations with the following quaint words:—"No part of surgery is thought to be so easy to understand as that which relates to fractures and dislocations. This is the opinion of a considerable section of the general public. They regard bone-setting as no matter of science: as a thing which the most ignorant farrier may become soon and perfectly master of: nay, that he may receive it from his father and family as a kind of heritage." In the treatment of fractures POTT insisted on the importance of setting the fracture, at the earliest possible moment after their infliction, and that it is wrong to wait for pain and swelling to subside, as these and other symptoms of the injury are due to, and are best remedied by rectifying, the faulty position of the broken fragments. But the pre-eminent principle we owe to POTT is that, considered abstractedly, neither extension nor counter-extension can even be necessary on account of the mere fracture, i.e., on account of the mere fragments, of the broken bone, which if left to themselves, remain just as motionless—just as absolutely still, and with no little tendency to move—as these pieces of bone on the table. POTT shewed that nothing can move the fragments of a broken bone but the muscles which are attached to them, and that

the difficulty we meet with in making and in keeping up extension of the broken limb, proceeds from the muscles only. To extend the muscles by putting the limb into that position which puts them into a state of tension is, if not to irritate them and cause them to offer resistance, at all events to give them their greatest power whether of displacing the fragments of the broken bone, or of opposing their reduction or setting. On the other hand putting a limb into such a position as shall most relax the whole set of muscles belonging to or in connection with a broken bone must best answer the purpose of incapacitating the muscles from acting upon it, and must remove the resistance they have it in their power to make attempts to reduce or set it. It follows that such a position of the broken limb as will best relax the muscles, must be the best for setting the fracture and for keeping it set afterwards.

A moment's reflection will prove to you that this is generally the position which the patient naturally puts a broken limb into, in order to obtain ease until he gets proper assistance. POTT insisted, and we all know it to be true, that when people are brought to hospital with the femur broken, we seldom or never find them lying in the *dhoolie* or palanquin with the leg and thigh straight and resting on the calf and heel; but, on the contrary, we almost always find them with the knee bent and the broken thigh lying on its outer side. POTT treated fractures of the thigh in this position, and I recollect STROMEYER, when he visited Netley, describing the evil results of extension in the treatment of fractures during the Franco-Prussian War, and stating positively that the position described by POTT, without splints, gave infinitely better results than extension and appliances made immovable by starch, gum, or plaster of Paris.

It is, of course, true that the extension by immovable appliances can only be intermittent, and that moreover we now have the pulley and weight with which to maintain continuous and non-irritating extension in fractures of the thigh; but it is a question of some importance how far this method could be employed in military surgery or in time of war, and it is a method which is certainly not applicable to any fractures but those of the femur. In the upper extremity, POTT's principle is even more obvious than it is in the lower, and yet I see it stated in the last new text-book on surgical anatomy that the proper way to set fractures of the arm is to extend the limb. POTT states that with the arm extended the difficulty of setting a fracture is very great, and it is very painful to the patient; while if the arm be kept in the extended straight position, the fracture will inevitably be displaced and lie uneven. But we now can go much further than this. There is no fracture of the upper extremity which is not practically set by simply raising the arm and flexing the forearm. Fractures of the upper extremity, of the shaft, and of the lower extremity of the humerus, as well as all fractures of the forearm, including that of the lower end of radius, are all set by this easy manipulation. In other words, directly the forearm is bent in any of these fractures, and the muscles in connection with the broken bone put out of action, there is no more real difficulty, and hardly any more pain, in placing the ends of the broken bone in

apposition, and in keeping them so, than in doing the same thing to the fragments of the broken humerus which I hold in my hand. The knowledge of this fact is the key to the simple and easy treatment of fractures. No doubt the surgery of broken limbs is susceptible of improvement, as for instance by LANOWSKI's method by rapidly hardening the callus by massage and movement of the neighbouring joints, but POTT's principles can never for a moment be lost sight of.

The general position with regard to fractures then, comparing POTT's day with our own, is this:—The obstacle to the setting of fractures is the action of the muscles. In POTT's time there were two available means of overcoming or counteracting this action, namely, (1) extension, and (2) position, and POTT proved that extension is both unnecessary and painful. Modern surgery is armed with three ways of doing the same thing, namely, (1) extension, (2) position, and (3) chloroform. If extension is employed, chloroform ought to be given in the setting of all fractures; but if position is relied upon, and it is entirely sufficient, the pain is so slight that chloroform is unnecessary in the setting of any fracture, but the one exceptional fracture of the thigh. Not the least interesting feature in the connection between POTT's principles of fracture treatment and modern surgery, is the fact that the great surgeon himself once sustained a compound fracture of the leg. Amputation was decided on at a consultation of the St. Bartholomew's Hospital Staff, and was within an ace of being performed, when the opinion of one alone of the consultants prevailed, and the limb was preserved. The fracture then united without inflammation, exactly like a simple fracture, and POTT attributed this happy result to the circumstance that when the protruding end of the broken tibia was reduced, the valve-like opening of the soft parts closed behind it in such a way that the entrance of air into the wound was prevented, thus accidentally foreshadowing, a century in advance, the scientific aseptic method of the immortal LISTER. In 1866, exactly 110 years after POTT's accident, which so nearly led him to the discovery of Listerism, LISTER himself treated a compound fracture in the Glasgow Royal Infirmary by methodically preventing the entrance of air into the wound by means of an artificial scab of lint, blood, and carbolic acid; and in this way he opened up the new era, which we call, and which is in truth, modern surgery.

The connecting link between PERCIVAL POTT and modern surgery is SYME. POTT died in 1788, SYME was born in 1790. Throughout his career which ended in 1870, SYME upheld and consolidated POTT's surgical principles. But he was not the man to follow any beaten track, and during the fifty years he practised and taught, he introduced many new measures into surgery which will perpetuate his name as long as medicine lasts. In 1823, when barely three and twenty years of age, he performed amputation at the hip-joint for the first time in Scotland; and in 1829 he excised the whole of the upper jawbone for the first time in Great Britain. A report of the latter case reached the *Lancet* and was published with the following editorial note in a bracket:—"We need no ghost from the grave to tell us what has become of the patient," but a

month later the *Lancet* had the pleasure of recording his complete recovery. SYME established the operation of excision of joints in England: his operations on aneurisms have never been surpassed in boldness and originality; he showed that amputation of the whole arm with the scapula is a feasible procedure; and he was the first surgeon in England who successfully removed the whole tongue.

It was not alone in great things that SYME excelled. It is to him that modern surgery owes the simplest and most perfect operation for harelip: the only faultless amputation known, that of the foot by the heel-flap; and the easiest and most lasting method of curing organic stricture of the urethra. In harelip SYME demonstrated that the way to close the gap and at the same time make an absolutely straight lip, without any inequality or notch, is to entirely remove the margins by an incision which terminates on either side in the straight part of the lip quite beyond the angles of the gap. This plan is applicable to all cases of the deformity, single or double, and in no other way can a perfectly straight lip of uniform thickness throughout be obtained. This is a photograph of a case of double harelip operated on by SYME's method seven years ago, in which the cicatrix in the probolium has unfortunately become affected by keloid. Not only is there a full lip, straight, and without even the slightest trace of a notch, but you cannot see any sign whatever of cicatrix in the lip itself, and curiously enough the keloid does not affect any part of the lip. In fact there is no cicatrix in the lip, and what cicatricial tissue there was, after the operation, must have been absorbed; otherwise, it would have been affected by the keloid growth. With regard to SYME's amputation I need merely remind you that the tendency of all modern surgery is to make amputation flaps of skin, and it will be sufficient to quote the opinion of SIR WILLIAM FERGUSON about SYME's amputation in particular. FERGUSON says:—"I know of no amputation—no style or kind of amputation—which deserves more high consideration. There is everything associated with it to lead to perfection in our modern estimation of such a proceeding: a long stump, and a perfect covering to the end—a covering more perfect than that of any other stump: for the reason that the very bit of soft material on which we naturally stand, is still preserved for the future basis of this support. It is the greatest addition to amputation in modern times."

The great principle SYME enunciated with reference to organic stricture of the urethra (which we now know to be true) is that no stricture through which urine can pass is impermeable, and that organic stricture can be cured by what is called dilatation, and by nothing else. Dilatation in the surgical sense of the term consists in passing a bougie through the stricture, using a larger one every third or fourth day till the full size is reached, and then continuing to pass full-sized instruments afterwards until the stricture is cured. The remarkable circumstance about this result is, that it is the passage of the instrument over the diseased surface which effects the cure, and not any mechanical stretching or dilating by multiple splitting. The treatment can be shortened by dividing the stricture either by internal urethrotomy, or by splitting it with a

Holz's dilator; so that a full-sized bougie can be passed without delay at the first sitting. The disadvantages of internal urethrotomy are that the cutting instrument is out of the sight and of the direction of the finger of the operator, and that the cutting cannot be confined to the diseased part alone of the urethra. On the other hand, with a properly made dilator such as this, which MOORE, ARNOLD of London made for me, nothing but the strictured part of the urethra is split, and it cannot injure the healthy portions of the urethra; in point of fact they are never injured or interfered with by it in any way.

The next noteworthy phase of SYME's genius, which has had a remarkable effect upon modern surgery, was his almost intuitive perception of the cardinal point or essence, not only of an obscure case of disease, but also of new procedures and propositions in surgery. When SIMMONS brought chloroform to the notice of the profession, SYME very quickly perceived the nature of its action, and laid down rules for its administration, which have been proved by clinical experience, and by the experiments of the Hyderabad Commission, to be entirely sufficient when strictly followed to ensure the safety of the patient.

SYME's rules are and I beg you will consider them well:—"The points we consider of the greatest importance in the administration of chloroform are, first, a free admixture of air with the vapor of chloroform, to ensure which a soft porous material is employed, presenting a pretty large surface, instead of a small piece of lint or any other apparatus held to the nose; secondly, if this is attended to, the more rapidly the chloroform is given, the better, till the effect is produced, and hence we do not stint the quantity of the chloroform. Then, and this is the most important point of all, we are guided as to the effect not by the circulation but entirely by the respiration; you never see anybody here with his finger on the pulse while chloroform is given. *We never continue the inhalation beyond the point when the patient is fully under the influence of the anæsthetic.*" Finally SYME accepted and adopted LISTERISM as the perfection of surgical science, in that it keeps away or removes from wounds every source of external irritation and contamination which can interfere with the natural processes of healing or cicatrization. The LISTERIAN principle came to SYME as the most fitting termination of his labors in surgery, and he welcomed it with the quiet satisfaction of a successful general who has taken a leading part in an arduous campaign which ends in long anticipated victory.

This brings us to the consideration of the direct influence of SIR JOSEPH LISTER on surgery. However much the teaching of FORT, and later of SYME and his contemporaries, had led up to the antiseptic principle; or had, as it were, prepared the way for it, it came eventually as a surprise, and it revolutionised the surgery of the civilised world. The change was complete and final, though LISTER has since improved his methods, as the principle has been developed and circumstances have seemed to require it. The antiseptic method of LISTER showed us exactly how to attain the very thing surgeons had been striving after for so long, but which no one had previously discovered. No surgeon had made greater efforts in this direction than the French. I spent the year 1855

studying medicine in the Paris Hospitals, first in the service of ALMOND GOSLIN at the St. Louis Hospital, and later in that of MARSENGUE at the Hotel Dieu. ALMOND GOSLIN thought he had discovered the passages for surgical ferrets and blood poisoning in lichen dressings of alcohol. He was undeceived by one of the worst outbreaks of pyæmia in the St. Louis Hospital, which it is possible to imagine—one of his patients actually died of pyæmia after the amputation of a finger. MARSENGUE worked in a different fashion. His idea was that it was impossible to keep the germs of putrefaction, whatever they might be, out of wounds, and he therefore endeavored to prevent organic fluids from collecting in them, by exhausting them with an air-pump—which the patient had to work himself—and which was, on this account, impracticable. In other places it was hoped that by giving patients more cubic space in larger, better constructed and better ventilated hospital wards success would be obtained. As to the value of this plan many of you may recollect what happened here in Calcutta. The Medical College Hospital was very nearly condemned as unfit for the treatment of surgical cases on account of inveterate pyæmia and erysipelas. At one time all the surgical patients were placed in tents, but, if anything, the erysipelas and blood poisoning were worse in the tents than they had been in the wards. All other attempts to successfully stamp out septic processes in wounds failed, and there is no more to be said about them, but that they failed because they were not LISTERISM. The changes brought about by the introduction of the Listerian principle were mainly two-fold, one immediate, and the other remote. The immediate change was that hospitals in every part of the world, which had previously been considered unhealthy, became healthy under the antiseptic system, and it was found possible to keep surgical wounds absolutely free from sepsis and infection, no matter in what hospitals they were treated. The remote changes effected by the Listerian principle in surgery is very ably explained in WATSON CHEYNE's paper on "Modern methods or wound treatment" in the *Lancet* of 17th November 1894. He shows that in the surgery of compound fractures and dislocation, in that of the veins, of diseased joints, of hernia, of the abdomen, thorax, and brain, of cancer, of gland disease, of gangrene and of many other conditions too numerous to mention, a vast alteration in practice has occurred, which, from a purely surgical point of view, is entirely due to Listerism and that the area of surgery has been enormously extended and expanded in almost every conceivable direction. MR. CHEYNE truly states that formerly amputation was performed in compound fractures, in cases where the limb is now saved with certainty. It is a mistake however to condemn our predecessors on account of the amputations, they were mostly compelled to perform for compound fracture. In ordinary cases, in the pre-Listerian days, amputation was often the best treatment available, and many a patient lost his life owing to humane attempts to save limbs, which afterwards became the seat of fatal sepsis. I remember an experience of a surgeon who was a surgeon who was with "Banting's division" during the American Civil War.

A soldier was shot through the elbow joint. The surgeon advised amputation. The soldier objected and vowed that if he recovered he would shoot the surgeon who took his arm off. After a consultation the operation was performed and the man was sent to a hospital in the rear of the army. When the war was over the surgeon was walking in New Orleans one day and met him, and instead of shooting him the latter told him that he owed him his life. In the hospital to which he had been sent after the amputation he saw many soldiers with wounds like his own, in which the limb had been preserved, but they all died. He was the only one of the whole lot who recovered, and the amputation therefore in his opinion saved his life.

With regard to the theory of Listerism I do not profess to be an authority. The theory of sepsis you will doubtless accept as correct: but the theory of suppuration and of pyogenic organisms is, in my opinion, too simple on the one hand, and too far fetched on the other, to cover the whole field of surgery and inflammation that is embraced by Listerism. In WATSON CHEYNE's article pyogenic organisms are said to be the cause of suppurations in wounds, but I do not find a word about the inflammation which must precede it. There is no doubt that LISTER has demonstrated the power of the tissues to destroy bacteria, but the citation of this fact to account for the almost invariable union by the first intention which takes place in the operation for harelip, appears to me to give it undue importance. A more reasonable explanation is to be found in the impossibility of any collection or lodgment, either of fluids or of bacteria, between the surfaces of wounds, which, like those for harelip and ovariectomy, have a double exit for surplus discharges and exudations. When the wound is properly adjusted in these cases, the amount of exudation is sufficient to secure union, and no more. But if one or two stitches are put in too tight, the wound inflames in the track of the sutures and it will be lucky if union by the first intention is not prevented by the inflammation affecting the whole wound. Without attempting to reconcile opposing theories, however, we can state confidently that the Listerian principle arms the surgeon at all points in the treatment of wounds, which for practical purposes may be divided into three great classes. In the first class may be placed all operations, as WATSON CHEYNE puts it, through unbroken skin, and all traumatism in which the avoidance of septic or infective complications can be prognosticated or anticipated with certainty. The precautions and dressings in wounds of this class must be carried out in strict accordance with the Listerian plan, and they then heal by the first intention, without inflammation or suppuration all wounds in which union by the first intention without inflammation cannot be reckoned on with certainty fall into class two, which therefore embraces wounds of a doubtful nature as regards sepsis, i. e., wounds in which it is highly probable that sepsis has already commenced owing to a self-evident cause like delay in treatment, or to an obscure cause such as is found to be at work in many forms of abscess of the liver. Lastly this class includes the immense variety and number of wounds where sepsis exists beforehand: the type of which is to be found in SYME's amputation of the foot

for caries, with suppurating sinuses and surfaces which cannot be excluded from the operation wound. In this very large class of wounds antiseptic precautions and dressings are employed, but the essential factor in obtaining and maintaining asepsis is to keep them wide open, and convert them, as far as possible, into superficial wounds until they can be closed without risk. In abscess of the liver this is done by excising two or more ribs. In SYME's amputation for caries the heel flap must be kept wide open until granulation is established. It may then be brought into its normal position, and union by the third intention will at once be obtained.

Expense in wounds of the first class.—The dressings in wounds of the first and second classes must be antiseptic; but they need not be either irritating to the patient or expensive to the Government or municipalities who have to pay for them. In the Nizam's hospitals we are adopting the cheap antiseptic dressings recommended by NERVE of Cashmir in the *Edinburgh Medical Journal* of November last. They are cheap and effective, and do not involve the indiscriminate use of poisonous drugs like iodoform, which is not an antiseptic at all, and is of no earthly use except in soft chancre.

The third class comprises wounds, with double exits, such as those for harelip, and abdominal sections in which drainage is not necessary. In abdominal sections the most rigid antiseptic precautions are necessary during the operation to prevent contamination or infection of the peritoneal cavity; if drainage is required, these precautions have to be extended to the discharges, and Listerian dressings must be employed. But if the peritoneal cavity does not require drainage, the wound in the abdominal parietes needs no dressings. It should be treated as we always treat it, exactly like a harelip. Antiseptic collodion should be painted over it after the sutures are applied, and once a day subsequently until they are removed ten days later. In abdominal section whatever discharge or exudation there is from the wound under these conditions tumbles into the abdominal cavity, where it is absolutely safe.

Such is very briefly the practical position of wound treatment at the present time. It is the surgeon's duty to prevent sepsis in all wounds made through unbroken skin, and to arrest it without delay in all wounds where it already exists. Whether LAWSON TAIT can accomplish this object by enlarging his hospitals and by what he styles the strictest possible cleanliness; or other surgeons can do it by aseptic filtration dressings; or WATSON CHEYNE by true antiseptic methods, it is all one and the same thing—the fulfilment of the Listerian principle. No doubt before 1866 wounds did heal, and from time to time in the future will heal, without Listerism, but this is not the point. The point is that we now know how to protect wounds from both putrefaction and infection, and to ensure their union by the first intention, almost with mathematical certainty and precision, without inflammation or suppuration; and no one can pretend that we knew how to do this before 1866, or that we owe our knowledge to anyone but SIR JOSEPH LISTER.

It is not difficult to estimate at its true value the immense influence of the late SIR JAMES SIMPSON on modern surgery. Who actually found out that there is such a

chemical compound as chloroform is a matter of no consequence now. SIMPSON discovered its uses as an anæsthetic; it was he who established its employment on proper principles in surgery, and to him belongs the credit. I have quoted SYME's rules for the safe administration of chloroform, and SYME himself said: "I am very far from taking any credit to myself, all that I have done has been to follow the example of Dr. SIMPSON." The clinical value of SYME's rules is proved by the fact that those who follow them give chloroform with uniform safety all over the world, while those who do not follow them, and watch or depend upon the pulse, can not do so. This is not my own statement; it is what those who watch the pulse themselves state, that no one can give chloroform with uniform safety because it acts upon the heart, and that therefore a certain number of deaths are unavoidable. The heart theorists did not accept the clinical statistics of SYME's followers. They said "what is the use of your statistics, which simply shew so many administrations without a death, when we have deaths under chloroform every day, which we are convinced are due to direct failure of the heart;" and in 1889 they demanded that our clinical statistics should be abandoned or supported by experiments on animals with self-recording apparatus. Accordingly in virtue of the kindly and wise liberality of the Nizam, the Hyderabad Commission was appointed, on my suggestion, to determine once for all whether SYME's rules are right or wrong. The Commission proved that chloroform causes death by stoppage of the respiration and not by stoppage of the heart. One of the few points on which the Commission did not furnish any explanation was with reference to what occurs after the breathing stops; and it was for a long time supposed that asphyxia supervened, on failure of the respiration, and was the cause of death. This idea was shewn to be wrong by VICTOR HORSLEY's experiments on the mode of death in bullet wound of the brain. Formerly it was believed that when a bullet is fired through the cerebrum instantaneous death takes place from stoppage of the heart. VICTOR HORSLEY demonstrated that this is not the case; that death is caused by hydro-dynamic pressure on the respiratory centre and sudden complete arrest of the respiration. The mode of death is on all fours, to use MR. HORSLEY's own expression, with death from chloroform, and one tracing serves to illustrate both. The respiration stops—suddenly in bullet-wound of the brain, gradually, as a rule, in overdosing with chloroform—and there is no asphyxia. The heart being deprived of its nutrition runs down and stops, and so complete is the resemblance between the two that if no time is lost the breathing may be restored, in bullet wound of the brain, just as it may be in overdosing with chloroform, by artificial respiration.

The Hyderabad Commission not only proved that SIMPSON and SYME were right, but it rid modern surgery of the bugbear of direct failure of the heart under chloroform, and of chloroform syncope; and it is just as irrational to stick to it and to bring forward cases to prove that death from chloroform is due to direct heart failure; as it would be, in the face of HORSLEY's experiments, to assert that death from bullet wounds of the brain is due to syncope and not to stoppage of respiration. It is true that the

Hyderabad Commission's experiments were performed in India, but, if it is necessary to argue for this matter of fact, it is enough to remind you that they could not possibly have been performed in sufficient number to satisfy LAUDER BRUNTON anywhere else, and the effects of chloroform, no less than of bullet wound of the brain, are precisely the same in India as they are in Europe.

Another point which was left undetermined by the Hyderabad Commission, but which is more of physiological than of clinical and practical importance, is the question of the exact and immediate cause of the fall of blood pressure that occurs in all forms of anæsthesia produced by chloroform, or by ether, or by gas, or by asphyxia. To elucidate this PROFESSOR GASKELL was asked to make further experiments, for which the expenses were again generously met by the Nizam's Government. As the result of a series of very ingenious but complicated experiments GASKELL has been led to contend that the fall of blood pressure is actually the result of the action of the chloroform on the heart tissues, though at the same time he believes there is practically no danger to the heart in the administration of chloroform, and agrees with the Hyderabad Commission that the supposed occurrence of direct cardiac syncope is a myth. It is unfortunate that this opinion of GASKELL's, qualified as it is, should be taken as a reason for believing that chloroform is dangerous to the heart, although such danger is repudiated by GASKELL himself, who should certainly be the best judge of the limits of the peculiar action upon the heart in which he believes. Moreover, a fall of blood pressure is inseparable from all forms of anæsthesia at present known to us, and consequently if we are to give up chloroform because it causes a fall of the blood pressure, we must also give up ether, nitrous oxide gas, and every other form of anæsthetic. There is no necessity then, nor is this the place to discuss the reasonableness or otherwise of GASKELL's peculiar views.

I have only one further remark to make about the Hyderabad Commission, and I make it with an amount of pleasure which I shall not attempt to disguise. The success of the Commission's experiments was entirely due to DR. BOMFORD. It was he who recorded on the tracings of the manometer every fact as it occurred. If you examine the specimen tracing sent round, you will see what perfect work this was and what a tell it must have been to carry out. But this is not all. Many physiological facts were brought out by the Commission's research, for which DR. BOMFORD has never received the credit to which he is justly entitled. He discovered that the fall of blood pressure, which is produced by the direct action of chloroform, is not, as was previously supposed, dangerous; and that asphyxia does not raise but always lowers the general blood pressure. Lastly, DR. BOMFORD made it clear that the action of the vagus under chloroform, which up to 1889 had been universally regarded as a source of peril, is a safeguard; and this led to the remarkable and beautiful discovery that inhibition of the heart by the vagus can never do it anything but good, and that it is paralytic, and not stimulation of the nerve, which is dangerous and induces the heart block and a gray to injurious influence.

Finally as you all know, the acknowledged safety of chloroform in India has been accounted for in various ways by our brethren in England. It does not appear to have struck them that the real reason for the safety of chloroform in this country is that, for many years past, the principles of SIMPSON and SYME have predominated throughout the whole of India, and it is not too much to state that the general adoption of these principles in modern surgery in future will alone render the benefits of SIMPSON'S priceless discovery unlimited.

Gentlemen, I have finished. I have endeavoured to bring before you this morning some of the principles of surgery which have been handed down to us by men like POTT and SYME. Their greatness and success as surgeons lay largely in their profound knowledge of anatomy, their choice of simple procedures and methods of operation, and their undivided responsibility for everything connected with the treatment of their patients. We cannot every one of us be a SYME or a TREVEN—the beau ideal of a modern surgeon—but we can all follow great principles and noble examples; and of one thing I am quite certain,—India can and will produce her full share of great men in our beloved profession.

—:—:—

A RETROSPECT OF OPHTHALMOLOGY IN BENGAL.

BY LAL MADHUR MOOKERJEE, RAI BAHADUR, L.M.S., F.C.S.
*President and Teacher of Ophthalmology, Calcutta Medical
School, and President, Indian Medical Association.*

OPHTHALMOLOGY as an exact and accurate science is as modern as bacteriology. As a crude art, it is as ancient in Oriental literature as the Hindu Sastras. Away back in the Dark Ages, Asiatic practitioners of medicine recognised and wrote about and dogmatised on the treatment of most of the disorders of the eye that are known to ophthalmic surgeons of recent date.

With the invention of the ophthalmoscope a new era dawned upon the domain of ocular pathology and therapeutics, and with this scientific achievement have come all those advances in Western ophthalmic science and practice that give it so high a place when compared with the art as it is found in the teachings and practices of Orientals. There must always be given a recognised value to the advantages which Western ophthalmologists had over Orientals in their knowledge of ocular diseases and their treatment. From the teachings of anatomy and physiology with the West, there was an intimate knowledge of the structures and themes of the organs of vision, their special functions and changes from health to disease, which were rendered easy and manageable by the light of sound pathology and morbid anatomy. These were all advantages which placed the West on a much higher platform than the East. Yet the fact remains to the credit of Oriental ophthalmic art that, shorn of all these helpful scientific auxiliaries, our ancestors in medicine in Bengal and throughout Asia successfully combated nearly all the best known disorders of the human eye. Such diseases as conjunctivitis, iritis, keratitis, ulceration of the cornea, non-specific and specific ophthalmia, granular lids, ectropion and entropion, cataract in its various forms, the causes of faulty vision and blindness, were all treated systematically and very successfully.

It must be admitted, however, that while Oriental medical literature had its place in the archives of the learned, the flood-gates of knowledge were closed to all but a select few, and the bulk of Oriental practitioners were illiterate so far as book-learning went, and their practical knowledge, which was often exceptionally good, was gained by a species of discipleship and governed by the teachings of tradition rather than any written precepts.

With this preamble I come to the era which marks the dawn of Western light and education, not only in the province of Bengal, but throughout British India. My remarks, therefore, whilst they tend to portray the state of ophthalmic science in Bengal, have an intimate relation to the history and spread of this important branch of Western medicine throughout India; for Bengal was the starting point of the introduction of Western education in every science and art, as they are found throughout the Indian Empire of to-day.

The history of modern ophthalmics in India dates from the establishment of the Medical College in Bengal in the year 1835. Prior to this a number of surgeons of the old Honorable East India Company's service had opened dispensaries in various stations in Bengal, notably in Calcutta, where the poor had their ailments gratuitously treated and often at the entire cost of these doctors.

In these out-door infirmaries, as they were called, there were a few beds for operation cases, and here Western medicine gained many of its earliest disciples, who became useful and distinguished practitioners. Not however till 1835, that is the opening of the Medical College and Hospital in Calcutta, was any well organised effort made to teach anatomy and physiology. Sixteen years later Western ophthalmics found an able exponent in Dr. MARTIN, whose appointment to the chair of ophthalmic medicine and surgery dates from the year 1851.

His successors, Drs. ACHER, MACNAMARA, CAYLEY and JONES, have all been men of great ability, and have left brilliant legacies of their work behind them. CHARLES MACNAMARA, who is now one of the leading ophthalmic surgeons of London, gave India the first work of eye surgery and medicine based on Indian experience, and this book is still a valuable guide to our students, in spite of the gigantic strides that ocular therapeutics has made in the past two decades. I will deal briefly with some special points connected with ophthalmics in Bengal, and of necessity I can only touch the merest fringe of my subject, which has admittedly a very wide range. The world has been busy with ophthalmics, and never in the history of profession has there been such a profuse display of knowledge and original research in ocular therapeutics, as we have seen in Great Britain, America, France, Germany, and Europe generally at the present time. It is not my province to deal with new light and recent knowledge, but I am called on to sift the garnered grain of past generations, and to present, if possible, in a nutshell the work of others, whose lives and records are now matters of history. In Bengal we have ocular diseases common to India generally, but I am concerned only with this province, and the limit of time and space remind me, and you also, of the duty of brevity. My remarks therefore will scan such familiar disorders as cataract, ophthal-

nia, neopatorum, glaucoma, atrophy of the disc, and disorders of refraction and accommodation.

Cataract.—The occurrence of cataract in Bengal is very common, and this may be judged by the fact that on an average nearly three-hundred operations have been performed yearly in the Eye Hospital of the Medical College during the past thirty years.

The most generally performed and most successful method of operating for cataract in Bengal has been and is still by simple extraction of the lens without iridectomy, the pupil being previously dilated with atropine. The incision involves about one-third of the cornea, and is made as nearly as possible in the sclero-corneal junction. There is much in success which depends on the individuality of the operator, and this cannot be exaggerated. Clean steady fingers and a delicate dexterous touch, with a high moral appreciation of the responsibility, do more to make a record in successful ophthalmics than all the book reading in the world. I am able to corroborate this assertion by my own experience in watching the exceptionally able and dexterous operative work of my old teacher and friend, Dr. CHARLES MACNAMARA, a former professor of ophthalmics in the Calcutta Medical College Hospital. His modified linear extraction, which bears his name, involved no iridectomy. The pupil having been previously well dilated his incision so perfectly performed by a special knife of his own invention, left it an easy matter to introduce a scoop, and with a gentle pressure exerted upon the circumference of the lens, caused it to be rotated on its axis to find a rest in the concavity of the scoop, and thus delivered from the eye with the least possible disturbance of the adjoining structures. The lens with its capsule entire so freed resulted invariably in the most perfect success of vision possible.

Such too was the special individuality of PROFESSOR HENRY CAYLEY of our College, whose operative work with cataract was extremely successful from the combined methods of PROFESSOR MACNAMARA and VON GRAEFES. The success of these two Calcutta ophthalmic surgeons gave result of eighty-seven per cent. of cures by MACNAMARA'S method and seventy-seven per cent. by VON GRAEFES. It is important in this connection to state that these results were from hospital patients, in whom there was no choice of selecting suitable or unsuitable cases. The records of these surgeons in private practice, where selection was the rule, yielded far better results, and a success of ninety to ninety-five per cent. was nearer their average. Personally my experience during a practice of nearly thirty years, which has been guided largely by my association in work at the Ophthalmic Hospital for fourteen years with Drs. MACNAMARA, CAYLEY and JONES, had led me into selecting the operation for cataract usually performed by these surgeons, combined and modified, that is, a VON GRAEFES, the section being however purely corneal, and thus avoiding iridectomy in every possible case; and I may with gratification say that I have had results that equal those of my revered teachers.

The operation which I have been accustomed to perform for many years past is preceded by preliminary antiseptic precautions. I wash my face and hands and then cleanse the face, eyes and eye-brows of the patient with cotton and a solution of boracic acid (one grain to an ounce of water), the lotion being freely put into both

eyes while the patient is in bed. I now drop a freshly prepared 3 per cent. solution of cocaine into the eye to be operated on, which has already for two or three days been under the influence of atropine. The instruments are dipped in boracic lotion and then used. Special attention is paid to the knife which is tested before operation as regards sharpness and polish. I use a stop-speculum. The section made by a GRAEFES knife is corneal, and occupies nearly the upper third of the cornea. The left hand is used for the left eye, and the right for the right. The section is completed by cutting directly through the cornea. It is so cut through that it allows the edges of the section to come directly together. I then take the curette and place it on the sclerotic at the lower part near the cornea sclerotic junction and deliver the lens by pressure. I allow a little time to elapse if necessary for accumulation of aqueous to reveal any lenticular substance which may remain behind. The iris invariably gets into its place; if not, I set it by gentle manipulation or by allowing the rays of light to act on it. Sometimes it may be that I have to take the aid of the curette to adjust the section and to replace the iris. I then drop in a 4 grain solution of atropine to put the iris at rest, and apply a pad and bandage to both eyes.

I perform iridectomy, if the pupil has not responded sufficiently to atropine, or if the lens is hard and large, or if there is adhesion of the pupil. Where the lens requires to be removed by a vectis or a curette, or if by accident the iris be injured, and when the patient is incapable of enduring the quiet indispensable to the prevention of prolapse of the iris.

Concerning loss of vitreous in cataract operations.—This accident was held for many years by operators in Great Britain and on the Continent as a calamity involving insecurity to after vision in cataract operations. It is a remarkable fact that Dr. CHARLES MACNAMARA held and taught as far back as 1868 that loss of one-fourth of the vitreous was no bar to a perfect recovery of sight. His declaration on this matter was stoutly contested in London, but time has proved that MACNAMARA was right, and now our friends in Europe are reconciled to his views.

In 1880 I recorded the following statistics on loss of vitreous, which were read in my paper on this subject before the Calcutta Medical Society.

From the records of 926 cataract operations in the Calcutta Ophthalmic Hospital, I have found there was loss of vitreous in 122 cases, in which the methods of operation followed were:—

1st.—Upper section with iridectomy without laceration of the capsule in 99 cases.

2nd.—MACNAMARA'S operation in 21 cases.

3rd.—Lower section with iridectomy and laceration of capsule in 2 cases.

In these 122 cases, 69 recovered good vision and 5 fair vision and 28 cases failed.

The causes of failure were: 10 by iritis and 9 by atrophy of eye ball, 8 corneal sloughing, and 4 pano-phthalmitis. In 5 of the 28 unsuccessful cases the vitreous loss was very large, and in the remaining 23 less than a fourth of this fluid escaped.

With regard to the quantity of vitreous lost in the 122 cases, in 9 there was slight oozing, in 91 the loss was less than a fourth; and in 22 more than a fourth, amounting to almost complete escape of the humour.

It will be evident that where vitreous was lost the quantity had very little to do with the result of the operation, for where the largest quantity was lost as in the above mentioned 22 cases, 17 were cured and 5 only were unsuccessful, so that the percentage of success was 77.

In the cases where the loss was less than a fourth, as well as those in which vitreous only slightly coozed out, 72 were successful, and 5 partially so.

Of the 926 cases, 787 were quite successful. In 34 cases sight was restored partially, and in 155 cases the result was unsuccessful, or there were 84 per cent. of cures. But it has already been shown that the percentage of cures in cases where the vitreous was lost was 77 or a difference of 7 per cent.

Out of the 926 cases, 113 were soft cataract, and in them there was no loss of vitreous.

From my experience I have found that loss of vitreous as a complication, generally occurs in operating upon the second eye when the first eye has been spoiled by maltreatment by *muls* or quacks.

There is a remarkable augmentation of cures in recent times due probably to more extended knowledge, the selection of operations, and to antiseptics.

But there is a regrettable drawback that every ophthalmic surgeon in Bengal has to contend with, and that is, the need of a practical surgical instrument-maker to sharpen cataract knives, as all instruments have to be sent to England for repairs. Reverting to the subject of augmented success in cataract operations, the recent experience of the Calcutta Medical College Hospital, in which undoubtedly individuality as a feature conducing to success, has played an important part, together with modern antiseptics, we find the report of the Eye Hospital of Calcutta with a percentage of cures that has reached the high figure of 95.56 per cent, but 76.13 has been the average for the past six years. Surely this is an achievement which reflects considerable credit on Professor R. C. SANDERS, our present ophthalmic surgeon.

In recent times the prevalence of diabetes in Bengal has added largely to the occurrence of cataract, and it is remarkable that these patients derive considerable benefit from a judiciously performed cataract operation. The later stages of diabetes which usually terminate in nephritic changes, afford abundant evidence of the great value of the ophthalmoscope as a diagnostic agent of nephritic retinitis.

Ophthalmia Neonatorum.—Bengal is the land of mendicants. It is no exaggeration to say that a million or more of the people of this rich and fertile province are beggars. This fact is of enormous significance and interest, when it is found that over sixty per cent. of these helplessly poor fellow-creatures are totally blind, and further that over forty per cent. of these visionless orbits owe their destruction to ophthalmia-neonatorum.

Total disregard of the simplest hygienic laws in the lying-in-room, the absolutely careless neglect of cleanliness of the infant immediately after its birth, are usually responsible for more than half the blindness one sees in Bengal. Household therapeutics limits the treatment of sore-eyes in infants to poulticing the eye-lids with black sulphide of antimony, or with butter and lamp-black (*majul*), or washing them with milk and warm

water or warm infusion, and these ablutions are so faultily done as to allow the lids to encase quantities of purulent matter, and thus the destructive and corrosive changes of the corneal structures go on, till vision is hopelessly ruined. If only our *dhoias* or native midwives could be trained sufficiently to regard the vaginal discharges as peculiarly prone to infect the eyes of their infant charges, how much the number of Indian mendicancy could be reduced, and how much of happiness could be added to the blighted lives of our fellow-creatures. For the treatment of ophthalmia neonatorum I have found the early application of a two per cent solution of nitrate of silver as eye-drops most beneficial. Of course it is an eminently preventable disease, and if sufficient cleanliness be observed in washing out the vagina before birth, and in seeing to the eyes immediately after birth, it can with certainty be shorn of its ill effects. As soon as the head of the child is born, both eyes should be wiped with cotton wool before they are opened, to prevent infection by any discharge which may be present, and the nurse should be instructed when washing the child for the first time, to use different water for the eyes with a pledget of cotton wool. When this has been done, one drop of a two per cent solution of nitrate of silver should be dropped inside each of the eyes. Of course, while cleanliness is absolutely necessary in every case, it is only essential to guard the eyes of the infant by nitrate of silver solution as a collyrium in those cases in which there is a suspicion of impure vaginal discharges. Frequent cleansing of the eyes is a *sine qua non* of treatment, and while antiseptic solutions of such reagents as boracic acid, perchloride of mercury, permanganate of potash, &c., play a helpful part as aids, the destruction of the morbid germs which created the disease, is most effectually performed by nitrate of silver.

Granular conjunctivitis.—Is a very common affection amongst the poor, consisting as it does of the formation of granular trachomatous bodies in the conjunctival connective tissue. I have found it extremely prevalent in Bengal. It is undoubtedly due to mal-hygienic conditions of life. Among the various forms of treatment I have found nothing to equal dusting the lids with tannic acid both morning and evening, then once a day, and later on every other day. In the meantime keep the eyes scrupulously clean by the frequent application of antiseptic drops, such as boracic acid and perchloride of mercury. Tannic acid sets up sufficient inflammatory change to cause absorption of the neoplastic bodies. Sulphate of copper was much used in former days. We still apply the *lepis divinis* to granular lids. But I think tannic acid can better reliably take its place.

The various reputed specifics of a decade ago, such as acetate of lead, quinine dusting, solution of perchloride of mercury, and strong solution of nitrate of silver, have all had their day; but sanitary measures, general tonics, and tannic acid dusting, hold the highest place in affording relief and cure to this troublesome and painful disorder.

Glaucoma.—Glaucoma is another commonly prevalent disorder in Bengal. Iridectomy is the sheet anchor of cure of this most dreadful affection. In Bengal much difficulty is experienced in inducing sufferers from glaucoma to undergo the necessary surgical operation of

iridectomy, and so recourse has long been had to various other forms of relieving intra-ocular tension by means of leeching and by ordinary antiphlogistics, but more recently the discovery of the great therapeutic value of eserine, has placed in the hands of Indian practitioners a most accommodating and efficient aid. The use of eserine affords relief for some time, and by and bye the patient makes up his mind for an iridectomy. In many cases a fair field of vision is maintained by the use of eserine, while the further progress of the disease is cut short.

Atrophy of the disc.—In this common ailment, the use of eserine collyria, and the subcutaneous injections of strychnine, have afforded the best results. It is remarkable how prevalent this disorder is among excessive tobacco-smokers and in those who use gunja and alcohol.

Disorders of Refraction and Accommodation.—The rigorous enactments of the Bengal Educational Code and the high mental tension which arises out of the keen competition that marks the training and education of our youths of to-day, have resulted in a most deplorable augmentation of the errors of refraction and accommodation; and so we find boys and girls of twelve to sixteen years decorated with spectacles—a sight that would horrify our forefathers were they to return to their mundane sphere.

In past times Hindu and Mahomedan ophthalmic practitioners had to face the amelioration of a very small number of cases of disorders of refraction and accommodation, and they devised pebbles of sorts to meet these defects. But these huge and unsightly glasses of our Indian ancestors in ophthalmic medicine, have given place to the delicate and well made spectacles of modern opticians. So necessary has become a knowledge of sight-testing that every general practitioner must equip himself with the means of aiding his patients and affording them relief to many insidious neuralgic manifestations which owe their origin to defective vision, or to errors of refraction and accommodation. My remarks both in their scope and measure, have of necessity been limited and brief, and for this I offer my regrets. Much that might have absorbed my attention in the wide range of ocular therapeutics remains untouched, but I venture to hope my feeble efforts may incite and encourage others to lay their views and their special knowledge of ophthalmology in India before the profession through our medical journals.

In conclusion, may I plead for a more systematic and thorough training of students in our Indian colleges in eye diseases? The tendency at present is to make expert opticians but poor oculists. The prevalent idea is that a good cataract operator is a good ophthalmologist. There is nothing more fallacious and nothing more hurtful as an impediment to the advancement of truly scientific ophthalmology. We need our students to be something more than rule-of-thumb prescribers of spectacles or gougers of cataracts. They must keep in touch with the ever-enlarging field of ocular pathology and therapeutics, and be well grounded in the allied sciences of medicine.

The specialism of ophthalmics is a paramount necessity, but it exists as an aid, and should be a guide to the general practice of medicine in those reflex pathological changes of which the eye is so unerring an index and the ophthalmoscope so true and faithful a guide.

No man should set up as an ophthalmologist unless experience and special education give him the stamp of honest fitness for such an onerous assumption. His specialist is the busy physician's most valuable assistant. He provides him with skilled hands, educated eyes, and trained ears, to do and see and hear that which he cannot undertake to do.

For ophthalmics our colleges have all the facilities so far as materials to teach with, subjects to practice, or students to teach are concerned, but the time allowed for teaching this important science and art is in most Indian colleges extremely inadequate. In speaking of materials, I mean patients, not apparatus. There is a marked lack of scientific appliances for the teaching of ophthalmics in all our Indian colleges, and the course of lectures, both theoretical and practical, are insufficient.

Let me express the hope that a new era will soon dawn on our country, and may this be hastened by the unselfish and generous aid of every medical official in India, who will thus gain the gratitude of a nation that owes all for her advancement in modern medical science to England and to England's sons.

A MIRROR OF PRACTICE.

THREE CASES OF CYSTITIS, WITH MISTAKES IN TREATMENT ARISING FROM INADEQUATE DIAGNOSIS.

By WILLIAM HUNTLY, M.A., M.D., B.S.C.

Rajputana.

CYSTITIS, difficult in itself to treat successfully, is often aggravated by mistakes in diagnosis, and the three cases noted below are all of them examples of this:—

Case I.—This case came into my charge a number of years ago in an English provincial hospital. The morning after my arrival I walked through the wards in company with the house surgeon whose place I was filling, and at the far end of the ward lay a young fellow suffering from chronic cystitis. The board above his bed shewed he had been in hospital for three months, and it was covered over with the usual variety of prescriptions for cystitis. His bladder had also been washed out with various solutions, but both lines of treatment had been ineffectual, and his case was looked on as hopeless; the idea being that he was suffering from tubercular disease of the urinary tract. There was a history of consumption in the family to support this theory, and certainly the general aspect of the patient gave it some countenance.

Attracted by the seeming hopelessness of the case and hoping that perineal section and drainage might accomplish something, I entered into a fresh enquiry of the patient's life.

The patient had no recollection of any specific disease, and indeed this had already been ruled out of the diagnosis. In washing out his bladder I made a careful examination of all the organs, and came across a small hard lump about the size of an almond, occupying the epididymis of one of the testicles. Was this an extension of the disease from the tract, and if so, did it support the tubercular theory, or did it point to venereal disease?

From its clear, thin, glassy appearance, was of recent origin, and its smoothness rendered the differential diagnosis more difficult. Weighing the various points, although I could find no mark of an old cicatrix on the penis, I decided in favor of specificity.

On this theory I at once stopped all treatment and put the patient on full doses of anti-syphilitic remedies. Five weeks later the patient walked out of hospital,—cured of his cystitis.

Case II.—This case came to Jodhpur Hospital. He was in a wretched condition, skin and bone, and carrying constantly in his hand a little earthen pot to catch the fetid urine as it dribbled away.

His history, if the man's story is true, pointed to great carelessness existing in several hospitals. He had been at the main hospitals of several big cities, and there had received such relief which, temporarily beneficial, left the man in a worse condition.

The man had a cartilaginous stricture extending inwards for about half an inch from the meatus. At the time of coming to me a probe was with difficulty passed through this. The surgeons at the various hospitals had simply slit up the meatus and let the man go. They could not have done a worse thing to him. The secondary effects of the slitting resulted in an additional narrowing of the stricture, and the man's life was a burden to him. He was willing to let me do anything, and as I did not care to put him under chloroform in his weak condition I saturated the stricture and its surrounding tissue with cocaine solution.

The thickened cartilaginous material was then dissected out. After this was done the tissue round the sound portion of the urethra was still further cut away, and when sufficient of the urethra had been cleared and part of the spongy tissue cut off, the urethral walls were pulled out and stitched back to the mucous membrane, a new meatus being thus formed of fairly sound tissue. It was impossible, with the constant dribbling of decomposing urine, to keep the parts clean, but in spite of a stitch or two rotting away, the result was altogether successful. A few months later the man returned to tell me that his trouble was all gone, power over the bladder was restored, and he had so improved that at first I did not recognize him.

Case III.—In this case there was a history extending back for four years. He had been under unqualified native practitioners who treated him for gonorrhoea.

There was no obstruction to the urinary flow, but the urine was of aropy mucous character, and the man, as in the last case, much reduced in strength and spirits. The passing of a sound revealed the cause to be stone in the bladder. The sound in passing along, seemed to me to glide in a groove between two somewhat smooth stones, and the point in advancing impinged on a third. Examination by the rectum revealed a rounded tumour about the size of a small orange protruding into the bowel. It was evident that I was dealing with calculi of some considerable size. On the following morning I extracted 10 stones by perineal internal lithotomy. Of these ten, eight weighed about four ounces. The ninth stone weighed one ounce and all the nine stones were faceted in the same manner as are multiple biliary calculi.

The tenth stone was much larger than any of the others; it measured 2½ inches in length, 2 inches in width, and 1½ inch in thickness, and was over three ounces in weight. The total weight of the ten stones was thus over eight ounces. In a little over three weeks the patient left the hospital well.

Remarks.—The above three cases are all, I think, noteworthy. The first illustrates the care with which we should come to judgment on a case, and the necessity of fully considering and examining every little detail in a case of doubtful or difficult diagnosis. The other two cases tell their own tale.

THE TREATMENT OF CARBUNCLE BY THE TOPICAL USE OF CARBOLIC ACID, ILLUSTRATED BY FIVE CASES.

BY JAMES R. WALLACE, M.D., L.R.C.P. & S. Edin.

Case I.—A wealthy Jewish lady of 40, in fairly good health, had a carbuncle as big as a crown piece over the lumbo-sacral articulation. It was much inflamed and had been growing for ten days when I saw it. There were about six openings on its surface, and a slough could be seen through them. Healthy pus oozed from the apertures. A fine probe with a little cotton wool twisted on it, dipped into liquid carbolic acid, was passed into each opening every morning for sixteen days and the surface covered with boracic wool. By the 12th day the slough had broken up and came away, and though granulation was progressing healthily, the cauterisation was kept up for four days longer. On the 20th day the parts were quite healed. Vinum Ferrum was given internally and a simple mixed diet of solids was taken throughout. There was slight fever on the first day, and this had been present for over a week. It disappeared on the fourth day of the treatment.

To economise space and to obviate repetition, I will analyse the points of the remaining four cases, as the treatment in all was same as in Case I.

| Case. | Age. | Race. | Condition. | Duration. | Carbolic applied. | Cured. |
|-------|------|----------|------------------|-----------|-------------------|-------------|
| II | 55 | Italian | Feeble anemic | 21 days | 9 days | In 12 days. |
| III | 61 | Indian | Flabby, weak | 7 days | 16 days | In 20 days. |
| IV | 80 | American | Emaciated anemic | 5 days | 10 days | In 14 days. |
| V | 43 | Scotch | Anemic, diabetic | 19 days | 19 days | In 24 days. |

Remarks.—Following the plan reported by Surgeon-Captain E. HAROLD BROWN, M.D., in these columns some time back, I treated these cases of carbuncle with carbolic acid. Dr. BROWN recommends the use of crystals. I found crystals hard to manage, and used the liquid acid with a cotton covered probe, and it answered well. In all the cases fever was present, and had been so in some degree from the onset of the carbuncle. Within four or five days in each case, the temperature fell to normal and remained so. The acid caused only slight burning pain for a few moments. The burning and throbbing of the ever present carbuncular pain was removed within one or two days after the use of carbolic acid. In every case iron wine was given internally. The diet was in no way restricted, the patients being told to eat what they liked best.

The rationale of the treatment of carbuncle by the topical use of carbolic acid as first suggested, I believe, by Dr. HAROLD BROWN, is based on the pathology of this disorder as being akin to a circumscribed necrosis of the cellular and sub-cellular tissues of the integument, due to localised inflammation dependent on some form of morbid blood stasis of systemic origin. A lowered state of the general health and certain specific disorders such as diabetes are accepted as predisposing to this peculiar necrobiosis. It is, however, clear that though the origin of carbuncle is to be found in a hæmic dyscrasia, certain local products of the peculiar necrobiotic changes that attend it, if not counteracted or destroyed by some topical application, have a marked tendency to aggravate the development and growth of carbuncle. It is important, therefore, since the increase of the local necrobiosis is always attended with proportionate constitutional disturbance and risk to life, that these morbid processes be destroyed by some rational method based upon correct pathology. These ends seem to be fully served by the topical use of carbolic acid, assisted by a generous regimen and the use of iron wine. The first evidence of the remarkable therapeutic value of carbolic acid as a germicide, is seen in the disappearance of septic fever and the subsidence of local and constitutional nerve disturbance in the remission of all pain.

Surely in this simple plan we have something which supercedes the barbarous crucial incision, the excisions and the tedious and time-wasting poultices of our student days.

CACHEXIA STRUMIPRIVA.

As the result of numerous observations on dogs, a consensus of opinion is in favor of the existence and relationship between the thyroid gland and the sexual organs, and that extirpation of these organs considerably modifies the cachexia, especially if the spleen had previously been extirpated; but SCIOLLA insists that extirpation of the thyroid always, in dogs, lead to tetanic death, which is not prevented by previous removal of the spleen; as the blood, like the other tissues, directly suffers from the intoxication due to the absence of the thyroid, which is not necessarily a homöopæstic gland. MARAGLIANO found a diminution of the red-cells and a certain degree of leucocytosis, but both ALBERTONI and TIRRONI note the feeble power of the blood of fixing oxygen under these conditions; but while they admit the probability of this want of fixing power as due to alteration in the pulmonary epithelium after thyroidectomy, other writers maintain that there is no real alteration in the blood, and that the thyroid gland has no hematogenic functions.

OPIUM IN EPILEPSY.

THOUGH opium can scarce be regarded as a specific in the treatment of epilepsy, still Dr. JOSEPH COLLINS contends that it is an important adjuvant, that acting symptomatically, it prepares the way for and enhances the value of other an insipid measures. He advocates its use as particularly valuable in old or intractable cases, but he does not regard it in recent cases of idiopathic epilepsy. He more the treatment by giving three grains of opium (in $\frac{1}{2}$ to 1 gougars of α) every day for the first week, doubles the daily ever-enlarging very weak till the patient reaches 8 grains per α and be well gro α grains of bromide of potassium four times

The specialism system of treatment he claims (1) cessation of the lesser time, (2) the frequency of the but it exists as an α after treatment is lessened by more practice of medicine though relapse may occur in a period of which the eye is so α has been accustomed to having. mesocope so type and faithful.

OUR PICTURE GALLERY.

SURGEON GENERAL SIR WILLIAM JAMES MOORE.

K.C.I.R., M.R.C.S. Eng., L.R.C.P. Edin.,

L.S.A. Lond., F.M.S.

Honorary Physician to the Queen.

WILLIAM JAMES MOORE, born in 1828 at Hales-Owen Worcestershire, is the son of the late EDWARD MOORE, Esquire, Deputy Lieutenant and Magistrate for the county of Worcester and an old and respected medical practitioner. Sir WILLIAM was thus at an early age habituated to medical and surgical practice, as conducted in those days when bleeding had not gone out of fashion, and when microbes were unknown. He attended his lectures and hospital practice at the Birmingham Medical School, and immediately on obtaining the diplomas of the College of Surgeons and Apothecaries' Hall, then almost the summit of the student's ambition, he was appointed House Surgeon to the Queen's Hospital at Birmingham, in which capacity he remained for three years, taking also the diploma of the College of Physicians of Edinburgh.

Not caring to take his father's large and laborious county practice, in 1852 he entered the Bombay Medical Department, going to India with some little reputation as the winner of the prize offered by the Provincial (now British) Medical Association for the best series of surgical cases with comments published in the *Journal*. Also with a large amount of practical professional knowledge derived from his father's practice, and from his long residence in the Queen's Hospital; which knowledge afterwards proved of invaluable service to him.

On arrival in Bombay his desire was to be attached to the College and Hospital there, but he was first sent to serve with the Artillery in the Deccan and afterwards to serve with the Cavalry and Infantry on what was then called the Rajpootana Field Force at Neemuch and Nusseerabad. After some years in these then little known stations, he was ordered for service in the Indian Navy, to which, in those days, all the Bombay medical officers were liable. He served in a naval capacity, chiefly in the Persian Gulf and Red Sea for nearly two years and a-half, and was present with the Persian expeditionary force, for which he received the medal and clasp. While in the Persian Gulf, he published an account of the climate and of the principal diseases prevalent there, which at the time attracted some attention. While he was in Persia, the mutinies broke out, and his next appointment was medical officer to the Kutch Levy, a regiment formed hastily during the mutinies and disbanded immediately afterwards. While in Kutch, he wrote a description of the Runn of Kutch and of the province generally. He then received the appointment of medical officer to the European Sanitarium at Mount Abo; and while there, wrote a full description of this mountain resort, and also published his work entitled "Health in the Tropics or Sanitary Art applied to Europeans in India," and the first edition of a "Manual of the Diseases of India." On his term at the Sanitarium expiring, he was appointed medical officer to the Marwar Political Agency with headquarters at Jodhpur. Having become well acquainted with the Marwar State, he published an article "Marwar the Land of Death." For a short

Yours truly
W. J. Moore

time he was transferred as Acting Resident Surgeon of the European General Hospital, Bombay, where he introduced the practice of the subcutaneous injection of quinine. From the records of the hospital, he obtained statistics showing the relation of hepatic abscess and dysentery, which have been frequently quoted. From the Marwar Political Agency he was transferred to the Rajpootana Political Agency, and became Superintendent-General of Dispensaries and Vaccination for the province of Rajpootana. In this responsible position he travelled annually through the greater part of Rajpootana, becoming intimately acquainted with the people. As a result, he contributed an article on native medical practice in Rajpootana, and also a report on the use of opium on that district. For his conduct of the medical institutions of the province he frequently received the thanks of the local authorities and also of the Government of India in the Foreign Department. He was in Rajpootana during the famine years, writing a report on the famine in the different states, which was published in the *Gazette*. He also wrote for the *Calcutta Review* a paper on sanitary progress in India, and contributed various articles to the *Medical Gazette*, and other periodicals on Madura foot, malaria fevers, the Eurasian future, and other subjects. On leaving Rajpootana he was made a C. I. E. and Honorary Surgeon to the Viceroy. His next office was that of Deputy Surgeon General of the Presidency Division, Bombay and Aden. He occupied his little leisure by publishing a book "The other side of the Opium Question" and another "Health Resorts for Tropical Invalids," and a second edition of his "Manual of the Diseases of India." On the termination of his five years' service as Deputy Surgeon-General, he returned to England for a time, until re-called to assume the high post of Surgeon-General with the Government of Bombay. On his final retirement, after more than 35 years in the service, the members thereof subscribed for his portrait, the remainder of the money collected being devoted to scholarships for the hospital assistant class, in whom SIR WILLIAM had always taken the greatest interest, regarding them as the worst paid and hardest worked of Government servants. It must also be mentioned that he is the author of "The Manual of Family Medicine and Hygiene for India." The origin of this work was the offer of a prize by the Government of India for a manual suitable for the numerous individual families and office establishments then (before railways were so numerous) scattered over India in positions more or less remote from medical and surgical aid. This work has now reached the sixth edition. On leaving the service he was made a K. C. I. E. and Honorary Physician to the Queen.

Since then, at the request of the Government of Bombay, he wrote the "Immediate treatment of accidents and injuries" for translations into the vernaculars. Also a work "The Constitutional Requirements for Tropical Climates," also an elaborate essay "The Progress of Sanitation in India," published in the Indian volume of the transactions of the International Congress of Hygiene and Demography. Recently he was made Honorary President of the Tropical Section of the Congress at Budapest, contributing a paper on "Tropical Dietetics." DR. MOORE represents the Bombay branch of the British Medical Association on the Council of that body.

THE Indian Medical Record.

1st January, 1895.

THE INDIAN MEDICAL CONGRESS.

THE first Indian Medical Congress, held in Calcutta, was opened on the 24th December 1894. LORD ELGIN, our Viceroy, and SIR CHARLES ELLIOTT, the Lieutenant-Governor of Bengal, graced the inaugural ceremony with their presence. The large hall of St. Xavier's College was crowded with doctors and leading citizens. The local profession mustered fairly, and the officers of the Indian Medical Service were in great force. Altogether the spectacle was an imposing one, and nothing seemed wanting to make the inauguration of the Medical Congress a brilliant success—for such it really was. LORD ELGIN opened the proceedings with a speech, which followed by the address of SIR CHARLES ELLIOTT, plainly shewed that the Government of India and that of Bengal were both firmly imbued with the importance of such a gathering as this Congress of doctors, and that the authorities in India fully realised the benefits that can and should accrue to this country by the discussion of such a subject as preventive medicine in its varied relations to tropical disease. Both these gentlemen acquitted themselves with excellent taste and ability, proving that the State in India is prepared to do its duty in all that concerns the health of its subjects in this Empire. The address of SURGEON-COLONEL HARVEY, which we reproduce elsewhere, was an exhaustive, masterly and well-considered presentation in most of its aspects. DR. HARVEY's review of the development of medical work, medical education and sanitation in India, is highly interesting and instructive. The solution of the great problem of financing hygienic reform in India was met by his suggesting a tax of one anna per head of the population, which would yield so large a "Sanitary Fund" as Rs. 13,000,000! DR. HARVEY did not tell us the cost of collecting this tax and assessing the balance. It is an easy matter to do a sum in simple multiplication and division, but we ought to reckon a little for subtraction also, and we fear the "little" in this instance would greatly reduce the thirteen millions. We have also to consider the fact that India's millions are so poor that it would be hard to find 40 per cent. of the masses able to afford two pice or half an anna through the long wearisome toiling 365 days of any year of their poverty-stricken lives, to pay even this small tax of "three farthings" which DR. HARVEY suggests. DR. HARVEY's prophecy of a "Sanitary Eden" for India may well be considered an "airy nothing," for India will have to be worked at half its present cost for the up-keep of official extravagance before one step can be taken in solving the financial aspect of this great sanitary problem. It was extremely pleasing to hear DR. HARVEY give expression to his feelings of sympathy with the local profession, and we believe these to be genuine. But DR. HARVEY could not escape from the temptation of claiming a monopoly of "Government hospitals for Government servants," nor indeed could he divert his "official" mind for a few brief

moments of the glamour that surrounds the "Service" of its self-declared superiority and exclusiveness. To harangue a mixed assemblage of private practitioners and local graduates on the subject of an OPEN AND EQUAL TERMS OF COMPETITION for the Indian Medical Service held in London and on the exceptional fitness of such a state of things, since the system involved the "getting of the best men" was altogether out of form, and in very questionable taste before an audience that was largely Indian, especially when it is all but too well known that competition to the Indian in England is a very different thing in the great matter of expense, when compared to the Englishman who simply crosses the street to enter the examination hall. It is hardly just to call such a competitive test a fair one, when it is remembered that a strong prejudice exists in London against admitting Indians into the Indian Medical Service, and it is a fact that they are excluded. It is one thing to have an honest law, it is quite another thing to obey it honestly. Let the examiners in London answer this oft-repeated charge made against them. Under any circumstances the cost of proceeding to England to compete in such an examination robs the system of all its fairness to Indians.

The sop offered to Cerberus in the opening of a hospital in Calcutta to be officered by non-officials is said to be an evidence of the desire on the part of Government to do justice to local practitioners. We fail to see it. The hospitals of Calcutta are *not* Government hospitals. They were built from funds raised by *private* benevolence for the poor and the PUBLIC COFFERS provided a portion. Has the Government of the country become so autocratic and despotic as to claim all public hospitals as its own property and to deny the public voice of the people of the country any share in their management and control? Who are Government officials but the servants of the people. Yet in India we are made to feel that India has to be governed for officials by officials. Hence it is possible for an official to defy public sentiment and crush the aspirations of the people of the soil by such utterances as Dr. HARVEY's, regarding the perpetuation of the monopoly of civil hospital appointments by *military* officers. We shall have more to say on this subject later on, and so we pass to more congenial topics. Surgeon-Colonel HARVEY's clever handling of vital and economic statistics was quite a feature in his address, while the general tenor and literary style of his remarks called forth the acclamations of his distinguished audience. But for the controversial element so unhappily thrown in and the tendency to shew up the failings—few and far between as Dr. HARVEY was compelled to admit—of the local profession, which detracted from the freely urged expressions of sympathy with our brethren outside the higher services in India, we feel certain that Dr. HARVEY's address will be read with interest and profit all over India.

Dr. ERNEST HART, the well-known and talented editor of the *British Medical Journal*, seconded the vote of thanks to the Viceroy in an excellent little speech. His mission in India is to spread the knowledge of hygiene and to make a strong effort to convince the people of India that cholera and fever are both propagated by impure water, and that both these scourges can be prevented

by a pure water-supply. We feel sure that Dr. HART will be cordially welcomed everywhere in his tour throughout India, and we wish him for India's sake, the fullest measure of success in his noble mission. The programme of the Congress is a heavy one. In the section of Medicine 39 papers were read, in Surgery 19, in Obstetrics 14, in Pharmacology and Indigenous Drugs 16, in medico-legal Medicine and Public Health 10, or in all 98 papers. It is believed that nearly 200 papers were submitted to the Congress, and it is quite possible that many of those that were unread at the sections will be printed and published in book form by the Congress Committee. We are not aware whether the privilege of publishing these papers will be confined to the Official Report of the Congress Transactions, but we feel sure that if they are handed over to one medical journal to publish, they ought to be given to *all*. The tendency of the Congress Committee to favor cliques has been markedly and regretably strong and so was their blameable inconsistency and meanness in trying to pay off old scores, a feature which was carried to a most lamentable degree of personality. We shall have more to say by and bye on this matter, but for the present we shall wait the development of the next phase of this question in the favoritism shewn in the publication of papers. We present in this number the address of the President of the Congress and the Presidential addresses for the sections of Medicine, Surgery, and Ophthalmology, and we hope to publish other sectional addresses and papers in coming issues.

The sectional address published are all highly interesting. Recreation and amusement were not left out of the programme of the Congress. The various outings for members were much enjoyed and the entertainments given by the President, Surgeon-Colonel HARVEY, at the Town Hall and by RAI BAHADUR LAL MADHAB MUKERJI, the President of the Indian Medical Association, and by Dr. JOGENDRO NATH GHOSH, were very successful.

—:O:—

THE CAUSE OF ENTERIC FEVER IN THE BRITISH ARMY IN INDIA.

COMMENTING on the article in our issue of the 16th October last on the cause of enteric fever in the British army in India, in which we suggested that the defective personal hygiene of the British soldier may explain the extraordinary difference between the liability of the European and that of the native soldier to enteric fever, *The Statesman* remarks that "there may be something in this but not enough, we suspect, to account for the facts. Valuable light would be thrown on the point, by a comparison of the liability of European soldiers to the disease with that of European officers of the same age, who practise ablution as frequently and are as careful about their teeth as the sepoy. If, as we suspect would be the case, it were found that the officer is little, if at all, less liable than the soldier, the theory that personal hygiene is the chief factor would be disposed of." We thank our contemporary for having raised this issue. We do not think that it is quite necessary, however, to consider how the disease affects European officers and European soldiers of the same age. In considering whether or not personal hygiene plays a part in the causation of enteric fever

it should, we think, render our first article in this connection satisfactorily conclusive or lend material support to our theory if statistics show that European officers in general are very much less liable to the disease than are European soldiers in general. Acclimatisation and susceptibility, it is generally conceded, afford one explanation of the marked disparity in the number of cases of enteric occurring in the European and native armies. Personal hygiene, we have suggested, affords another explanation of that disparity in numbers.

Considering then these three factors non-acclimatisation, susceptibility, and defective personal hygiene in the etiology of enteric fever, if it be shewn that the European soldier, in whom all these causes operate, is extraordinarily more liable to the disease than the native soldier, in whom all these causes are more or less absent, and who is more or less immune to the disease; and if it be further shewn that the European officer, in whom non-acclimatisation and susceptibility only operate, is much more affected by the disease than the native soldier and much less affected than the European soldier, then the part played by acclimatisation and susceptibility in the causation of enteric is represented by the extent to which the European officer is more affected by the disease than the native soldier is, while the difference between the liability to the disease of the European soldier and of the European officer, represents the importance of personal hygiene in reference to the etiology of the disease. In order then to give support to our suggestion that personal hygiene forms an important factor in causing enteric fever, all that it becomes necessary for us to shew is that there is a wide difference in the extent to which European soldiers and European officers are affected by typhoid fever. As the Sanitary Reports for the years 1891 and 1892 (on the figures furnished by which our previous article was based) do not give the number of cases of enteric among European officers of the Army in India, we had to make application for this information; and we are indebted to the courtesy of the Statistical Officer with the Government of India for the following table:—

Statement showing the number of admissions from enteric fever among the officers of Her Majesty's British and Indian Armies during the years 1891 and 1892.

| | Bengal. | | Madras. | | Bombay. | | Hyderabad. | | India, Contingent. | |
|------------|---------|-------|---------|-------|---------|-------|------------|-------|--------------------|-------|
| | 1891. | 1892. | 1891. | 1892. | 1891. | 1892. | 1891. | 1892. | 1891. | 1892. |
| British .. | 35 | 41 | 10 | 6 | 6 | 8 | .. | .. | 51 | 55 |
| Indian .. | 6 | 9 | 2 | 3 | 3 | .. | .. | .. | 11 | 11 |

The reports of the Sanitary Commissioner with Government shew that the total number of officers of the British and Indian Armies was 6,204 in 1892, and 6,391 in 1891; so that the sixty-six and sixty-two cases of enteric fever recorded for those years, represent 10·63 and 9·70 per mille of strength. Hence the number of cases has been:—

- Among Native Soldiers, 0·4 per mille of strength in 1892.
0·3 per mille of strength in 1891.
- Among European Officers, 10·63 per mille of strength in 1892.
9·70 per mille of strength in 1891.
- Among European Soldiers, 20·1 per mille of strength in 1892.
20·4 per mille of strength in 1891.

This, we think, points to a well marked difference in the liability to enteric disease, between European soldiers

and European officers, and makes our suggested factor in the causation of the affection viz., personal hygiene, a matter worthy of the consideration of military medical authorities. We quite admit the marked predisposition of the European to typhoid infection. In our last article we said that this "may be accepted as authentically established." There must, however be one or more other causes to account for this enormous disparity in the number of cases occurring in the European and Native Armies in India, and from a knowledge of existing circumstances, it struck us that there may be a relation between defective personal hygiene and enteric prevalence; and the figures which, on the suggestion of the *Seafarer*, we have been able to give in relation to typhoid fever among European officers, adds another circumstance to those we mentioned in our previous article in support of our theory. There may, of course, be other causes to explain the disparity, but we are inclined to regard defective personal hygiene as an important, if not the most important, existing factor to account for this difference. We expressed a very similar opinion in writing on this subject in our issue of 1st October 1892 and although we have noted with special interest and without prejudice, and have given to our readers as freely as we could, whatever may explain the fact of enteric fever becoming the scourge of the European Army of the country, we have had no reason to change that opinion. As yet the profession is only able to opine on this subject of the cause of enteric fever in the British Army in India, it is in search of light, and everything that can be reasonably advanced either in support or disproof of existing theories ought to be welcomed by the profession.

—:—:—:—

THE POSITION AND PROSPECTS OF THE MEDICAL PROFESSION IN INDIA.

We have from time to time referred to the position and prospects of medical men in general, their social status and their influence on society. We now propose to enter upon a consideration of all such matters in reference to the profession in India. There are permitted to remain in operation in this country, a series of evil influences which are altogether unknown, and which would scarcely be tolerated, beyond the limits of our peninsula—a series of regulations prejudicial to the profession, which make the lot of its members a hard and difficult one, and their prospects very gloomy indeed. It is not our desire to paint a mournful picture for the feminine or puerile gratification of evoking a sigh of commiseration for the local profession; but we feel it our duty to honestly defend our local brethren against a conservatism or blinding prejudice which stems their progress and bars and mars their social and professional advancement. The disadvantages under which local medical talent and private practitioners in India are placed, do not arise only from existing rules being very faulty, but also from the want of certain regulations.

We think that one of the most serious drawbacks to the proper recognition of the medical profession in this country is the want of an Act enforcing registration of all who are considered qualified to practice medicine, surgery and obstetrics, and in adequate and deterrent punishment not being

meted out to unqualified frauds. It is not only ruinous to practitioners, but absolutely degrading to the healing art to witness the unrestricted leniency with which those who are so disposed, are permitted to dabble in medicine. We need not remind our readers how easy it is for self-constituted vaids and hakims to spring up, and how unrestrictedly they are allowed to play with human pain and life. It is as easy and as common now-a-days to find individuals from the mere fact of having seen and smelt a few drugs in a sixth rate chemist's establishment for a few months or even weeks, posing as orthodox dispensers of medical relief. Unless then there be a distinct line of demarcation, such as registration under a Medical Act will provide, separating qualified practitioners from medical dupes, the profession must suffer in dignity as well as socially and pecuniarily.

The second disadvantage is that *all the medical services recruited locally are subordinate.* Let the perseverance, intelligence, and merit of these officers be what it may, they cannot hope to rise to the higher services.

"All ye who enter here abandon all hope of rising to higher or nobler things," is written in indelible characters on the portals of the subordinate medical services of India. Could there, we ask, be anything more disheartening to individuals and more destructive of ardour and improvement than this positive suppression of merit and ability? To be educated in India stamps one, *per se* in the official mind, as inferior. This is surely what our universities and colleges should resent as casting a reflection on their degrees and training. In the judicial, educational, and engineering services, locally educated men of mark may rise to the highest grades, whereas an English qualification is a *sine qua non* for admission into the higher ranks of the medical services, and even with such a qualification the subordinate cannot hope to be advanced to the higher rungs of the official ladder. A medical servant of the State should be permitted to rise *by dint of merit* from the lowest to the highest grades and ranks of the medical services. We hold that a certain number of Civil Surgeoncies and Army Commissions should be reserved annually for the more deserving Civil and Military subordinates. Some such concession as this would rob the present system of enforced residence in England for Indians and Anglo-Indians before "competition" is possible, of a fraction of its absolute unfairness and hardship to the people of India. We would strongly commend this suggestion to the higher authorities.

Thirdly.—There is the *total exclusion* of locally educated men and private practitioners from the higher teaching and public hospital appointments in India. This renders it absolutely impossible for them to rise to any eminence in the profession, or to become men of note. This discouragement of local talent is certainly absent in other educational branches, where the professional staffs are as worthily represented by locally educated men as they are by any others. Is it then one of India's weaknesses that she can turn out worthy professor of every subject except those included in a medical curriculum? This surely cannot be conceded; and one is naturally forced to assign less commendable reasons for this handicapping of local medical talent.

Fourthly.—Private practitioners in the country are very seriously *handicapped by the competition of official surgeons* whose State salaries make them regardless of fees and enable them to dispense advice gratuitously, while others again accept low fees which private practitioners ordinarily accept as their charges. The only alternative left to the private practitioner is to descend to a lower level of charges which scarcely compensate him for the worries and self-sacrifices which a practice involves. Government surgeons should be made to fix their fee at a sovereign or a gold-mohur per visit, and should not be permitted to take up the position of advisers to private trading and insurance companies, or to enter into any contract or annual arrangement for medical attendance on families. This rule gives the private practitioner a fairer and a more open field.

Fifthly.—The *disparagement of private practitioners by Government* in its refusing to accept the certificates of health or ill-health granted to Government servants by practitioners, and in its insistence on such certificates bearing the signature or counter-signature of a Government surgeon is a very bad feature. Such a regulation certainly does not raise a practitioner in public estimation, and bespeaks some distrust in his capacity or honesty. With a Registration Act, and with the understanding that certificates of such practitioners only who are registered under the Act will be accepted by Government, while improper or unprofessional conduct will be met by removal of a practitioner's name from the Register, the interest of the Government will be sufficiently protected against the vagaries which, it must be inferred from present rulings, Government fear may be perpetrated by private practitioners, and of which its officials are considered incapable of committing.

Sixthly.—The profession in India is more or less ignored by the *exclusion of private practitioners from any form of State decoration or honor*, such as Honorary Physicianships and Surgeoncies to the Queen as are bestowed on private physicians in England, and the Honorary Surgeoncies and Assistant Surgeoncies to the Viceroy as given in India to service men. Anglo-Indians and Indians on whom these honors have been conferred are or were in the service of the State. The distinctions then may be regarded as rewards for *official labors*. Professional merit has not been generally considered. The *profession* then has not been recognised or honored in these bestowals which are reserved for State appointments. If these decorations were from time to time given to meritorious private practitioners, the dignity and status of the profession in India would justly and advantageously be raised.

EUCALYPTUS IN ACUTE CORYZA.

DR. GRIAZNOFF says that the inhalation of eucalyptus affords the best means for cutting short an acute attack of cold in the head, provided treatment is early—that is, as soon as sneezing and watery discharge appear. The patient should tie a knot in his handkerchief, freely moisten it with eucalyptus, and then energetically inhale until the symptoms disappear completely. When the inhalation is resorted to within an hour or so after the first symptoms, the affection is usually cut short in from ten to thirty minutes. For those persons who dislike the odor of eucalyptus, add one-third peppermint oil, which increases the rapidity of the "cure." In children, several drops of the mixture should be sprinkled over the pillow.—*Novosti Terapii.*

COMMENTS AND NEWS.

RECRUITING FOR THE WARRANT MEDICAL SERVICES.

ONE of the features characteristic of the Eurasian and Anglo-India Association of Southern India appears to us to be its business activity. The Association does not merely exist, but lives a life of activity and usefulness, and it is imbued with a determination to avail itself of every circumstance which will benefit the community it represents. The suggestion, in our issue of 1st September 1893, that it was the duty of the Association to prevent manufactured Eurasians entering the Warrant Medical Service in opposition to para. 268, A. R. L. Vol. VI., was followed by a successful appeal by the Association to the Surgeon-General with the Government of Madras, soliciting that satisfactory proof of parentage be furnished by candidates; and now that parties have reason to believe that one of the candidates recently entertained has obtained admission into the service by misrepresenting his nationality, a Sub-Committee at their meeting of 5th December last have resolved to bring the matter to the notice of the Surgeon-General of the Presidency. We are glad to find that the Association does not waste time in vain talk and useless threats, but strikes directly at an evil. We do not decry the value and merit of the Indian, but rules are made to be observed and not to be broken, and an Association which recognises that a breach of any existing rules robs the community which it represents of any advantage, is to be congratulated in actively opposing such infringement of regulations. The present Surgeon-General with the Government of Madras is of the *smarter in modo fortiter in re* type; and he will not look unconcernedly on any violation of Government orders. We have no doubt but that if the candidate in question or any other is proved to have entered the service under false colors, he will be dealt with as he should be. All those interested in the Warrant Medical Service of their Presidency and in the Eurasian and Anglo-Indian community, should bring to the notice of their respective Associations all such who, since 1872, the year from which the Warrant Medical Services have been closed to Indians, have procured admission into the Services by representing themselves to be Eurasians. The Madras Association shews fully its willingness to take proper action in such matters. As we wrote in our issue of the 1st May last, "such exposure will not be an injustice to the victim; on the other hand, it would be a just and proper act, for justice does not shield delusion, but demands its prevention and exposure. The victim of such exposure is not deprived of what is his, but of what he has become possessed of by misrepresentation," and by depriving a fellow-subject of his State-sanctioned privilege. We think that the Surgeon-General of each Presidency should issue a circular in his command, intimating that as it has been brought to notice that individuals have procured admission into the Warrant Medical Service by wilfully misrepresenting their nationality in opposition to the condition that candidates for admission into such services must be of European or Eurasian parentage, as clearly set forth in the *Gazette* notifications, the Surgeon-General calls upon those who have entered the service under such misrepresentation to submit their resignations forthwith, and thereby to prevent their dismissal being gazetted on the Surgeon-General being made cognisant of their parentage as other than European or Eurasian. As a punishment for having deceived Government into the expense which their medical training has entailed, these individuals should be declared ineligible for further Government employ for as we said in our article of the 1st September 1893, an exemplary "exorcise of its rights by

Government in bringing to book one or two who can be clearly proved to have ridden rough-shod over its rules, will be the most effective way of checking any further infringement of its regulations."

A PHYSICIAN'S "AT HOME."

ON Wednesday, 26th December 1894, DR. LAL MADHUS MUKERJI, Rai Bahadur, gave an evening party to the medical profession, and SIR CHARLES ELLIOTT, the Lieutenant-Governor of Bengal, attended by special invitation to meet the doctors who are in full force in the city at the present time. Among the guests were the *élite* of Calcutta, including Indian noblemen and princes from all parts of India. Nearly 300 gentlemen were present. The street was decorated with bunting, and at both entrances triumphal arches were erected. DR. MUKERJI's palatial residence was beautifully illuminated, and the internal arrangements for the comfort of his distinguished guests were both luxurious and in exquisite taste. SIR CHARLES ELLIOTT spent some time in conversing with his host and with many of the guests, among whom were the Hon. MR. COTTON, the Hon. MR. C. E. BUCKLAND, DR. ERNEST HART, Surgeon Colonels HARVEY, LETHBRIDGE, LAWRIE, BOMFORD, CROMBIE, and many doctors from the Congress, both European and Indian, SIR JOTENDRO MOHAN TAGORE, PRINCE SIR JEHAN KADIR MIRZA, PRINCE BUNTEAR SHAH, SIR BHAGWAT SINGHI, Thakore of Gondal, NAWAR AGGAR ALI, the Hon. Justice GURU DAS BANERJI, and many leading physicians and general practitioners of this city, besides many well-known citizens. An excellent programme of music, jugglery, legerdemain, thought-reading, and ventriloquism was provided. The whole performance was most skilfully conducted. After refreshments were partaken, the guests dispersed, carrying with them the pleasantest recollections of DR. LAL MADHUS MUKERJI's hospitality. DR. MUKERJI, besides occupying a high position as an ophthalmic surgeon and as Principal of the Calcutta Medical School, is also President of the Indian Medical Association. The Lieutenant-Governor, in accepting DR. MUKERJI's invitation, paid him and the local profession a special compliment, for it is the first instance in which any Governor of Bengal has accepted of the hospitality of an Indian physician.

SURGEON-COLONEL HOOPER AND THE MEDICAL BOARD OF THE INDIA OFFICE.

THE Government *Gazette*, N.-W. P. and Oudh, of Saturday last, contains the following appreciative and well-merited official recognition of the services of DR. W. R. HOOPER:—"In connection with the approaching retirement from the service of Brigade-Surgeon Lieutenant-Colonel W. R. HOOPER, Civil Surgeon of Lucknow, His Honour the Lieutenant-Governor and Chief Commissioner desires to place on record his appreciation of the excellent and devoted services rendered by that officer to the Government of these provinces for a period which extends back to June 1861, when he entered civil employment.

After eleven years' good service in the Jail Department as Superintendent of the Central Prisons of Allahabad and Benares, he was, in September 1874, placed in medical charge of the important station and district of Benares, where the magnificent Prince of Wales' Hospital is a monument of his untiring energy in charitable medical work, as well as of his personal popularity.

In August 1891, as a reward for long and approved service, he was transferred to the Civil Surgeoncy of Lucknow, where he not only earned the approval of the Government, but gained the confidence and affection of all classes of the European and Native communities.

In 1881 he received the thanks of His Excellency the Viceroy and Governor-General of India, and between 1878

and 1893, on eight separate occasions, those of the Government of these Provinces, for the working of the hospitals and other medical institutions under his charge, and throughout a long career he has well upheld the high character of the service to which he belongs.

THE DOCTOR'S WIFE.

THE doctor's wife is an important factor in his success or failure. So thinks the *American Lunnet*. Where the wife takes a pride and active interest in her husband's work there will be success; but where she is, all complaint about being left alone and not content to share the life of the busy doctor, or to put up with its disadvantages there will be failure. DR. E. C. VALENTINE, in support of this opinion, tells a tale which we may reproduce in brief: He called to see a colleague. The latter was not at home, but his wife welcomed him, and asked his attention to a man she had on the operating table with his posterior tibial cut. She had controlled the bleeding with a neatly applied improvised tourniquet, but was afraid to attempt ligation. Just then the husband returned. She helped him proudly in ligating the vessel, and then patted him approvingly on the cheek. 'But dearest,' said the husband, noticing the soiled matinee and her blood-stained dress, 'you have lost the matinee in consequence, and your new dress is ruined.' Her proud and affectionate rejoinder was: 'What is a matinee or a new dress to seeing a good operation performed by a good surgeon, and that surgeon my husband!' Whether the husband pressed her in a strong embrace and rewarded her with kisses after the novel and romance fashion, or whether he experienced a feeling of dread or depression at thoughts of weighty shop-bills, the narration sayeth not. But with such a sympathetic and practical help-mate a practitioner should succeed.

THE CONSULTANT, THE PRACTITIONER AND THE PATIENT.

ALTHOUGH it is the rule and the tradition of the profession that a consultant should advise a patient only through and conjointly with his regular medical attendant, the rule is not uncommonly ignored. The *Lancet* considers that PERCIVAL's statement "Of the conduct of physicians towards apothecaries" represents the claims of the man who is in regular attendance to the consideration of the consultant; and as the regular medical attendant is acquainted with the hereditary constitution, habits, peculiarities of the patient, &c., he is able to furnish valuable information. A furtive consultation then may be unjust to the regular attendant, injurious to the patient, and prejudicial to the interests of the consultant himself. The consultant who spurns the help of the regular medical attendant and endeavours to form an opinion in fifteen or twenty minutes on complicated facts, incurs a heavy responsibility and does not secure himself against error; and though a patient may be entitled to any number of independent opinions, he is likely to find himself very unhappy in his multiplication of them; and he should not receive countenance in such folly from the consultant who should always co-operate with the ordinary medical attendant.

THE HARD LOT OF CIVIL ASSISTANT SURGEONS.

THE present want of consideration for the hard lot of Civil Assistant Surgeons is said by the *Times of India* to be regrettable. Although wages depend upon competition, and there are more lawyers than doctors, yet a pleader may rise from a manship to the exalted benches of the High Court, while an Assistant Surgeon starts life on the miserable pittance of rupees one hundred and has no better prospect than of rising to rupees two hundred after a life time of service. The salary of Rs. 400 asked for by them is considered

reasonable, considering the general services rendered. Surgeons are called upon to perform all manner of work, generally recognised and conceded that this class of medical officers have substantial cause for dissatisfaction, and this is indeed a great point gained towards a satisfactory settlement of their case. It is the first and most important step towards obtaining redress; for this being once admitted by a Government whose watchword may be said to be "Justice," we may be full of hope that redress will soon follow.

DR. HARVEY'S CONVERSAZIONE.

THE President of the Congress and his amiable wife, entertained the members of the Congress at a conversation in the Calcutta Town Hall, on Friday evening, the 28th December 1894. Colonel and MRS. HARVEY received their guests, and by the time LORD and LADY ELGIN entered the Hall, it was filled with ladies and gentlemen, a large and distinguished gathering including not only members and delegates of the Congress, but civil and military officers and leading residents of the city. The Town Hall was well illuminated and the decorations with bunting, ever-greens and plants were very pretty and effective. A military band supplied a good programme of music. Here and there scientific apparatus, including microscopes fitted with specimens, preserved flowers, electrical and chemical appliances, the phonograph, &c., afforded much pleasure and interest, while the guests promenaded the Hall conversing with each other. Tables laden with refreshments were lavishly provided. The gathering dispersed at 11 P.M., and all who were present will heartily accord to Surgeon-Colonel and Mrs. ROBERT HARVEY their best thanks for their genial reception of their guests and the enjoyable entertainment that was so kindly provided for them.

HONOR TO CIVIL ASSISTANT SURGEONS.

WE are glad to hear that Assistant Surgeon Chetan Shah, Khan Bahadur, Bhagwan Das, Fateh Chand, M.B., and Mehr Chand, Rai Bahadur, have been recommended for appointments in the Uncovenanted Medical Service. All of them are men of distinguished and meritorious service in the Punjab. Dr. Chetan Shah, Khan Bahadur, (Honorary Assistant Surgeon to H. E. the Viceroy) has been officiating as Civil Surgeon since 1874, and is the author of several medical works. Dr. Bhagwan Dass has been officiating as Civil Surgeon since 1882. Dr. Fateh Chand, M.B., M.S., after serving for nine years in the Department, went to England for further qualification and distinguished himself at the Durham University. On his return in 1889 he was appointed to officiate as Civil Surgeon. Dr. Mehr Chand, Rai Bahadur, (Honorary Assistant Surgeon to H. E. the Viceroy) has officiated as Civil Surgeon several times since 1878. Only one Assistant Surgeon in the Punjab, Dr. Gokal Chand (in charge of the Secretariat establishment of the Government of India for several years and at present private medical adviser to H. H. the Maharajah of Patiala) has been appointed to the Uncovenanted Medical Service.

We heartily commend this system of promotion to other local governments.

BRIBES TO MEDICAL MEN.

THE *British Medical Journal* sounds a warning note to medical men cautioning them of the coaxing wiles of patent medicine originators and the makers of new brands of wine and things of that ilk, advising them to refuse presents when accompanied by the offer of "a case of half a dozen or so for your own use free of charge and carriage paid, and we trust that after tasting it you will kindly see your way to recommending the champagne, &c., to your patients." The General Medical Council of Great Britain is on the alert and intends to deal severely with medical men who are rash enough to swallow such baits as the above and append their signatures to certificates praising perhaps worthless stuff.

HOW LONGEVITY IS OBTAINED.

THOSE who have gone to comparative strength and vigour far beyond the limit of the allotted span of human existence have assigned their longevity to very different causes. *The British Medical Journal* says that M. BARTHELEMY SAINT-HILLARE, a French scholar and politician, who recently entered on his 90th year full of physical and intellectual vigour, thinks that adherence to the old precept "early to bed and early to rise" with steady work during waking hours is the secret of long life. With MR. GLADSTONE the secret is a daily walk in all weathers, and giving thirty-two bites to every morsel of food; with OLIVER WENDELL HOLMES it was equability of temperature; DR. P. H. VANDER WEYDE, an American Octogenarian, ascribed it in himself to the benign influence of the study and practice of music. One old lady, aged 120, ascribes her longevity to single blessedness and M. FERDINAND DE LESSEPS to horse-riding. The assigned cause with some old people is directly opposed to that assigned by others, being with some abstinence from and with others indulgence in alcohol, tobacco, meat, &c. Our contemporary puts the whole secret in a nutshell when he says that "it is a sound constitution prudently husbanded."

CHEAP DOCTORING.

DR. MARTIN of Sheffield, speaking on medical ethics lately, loudly and strongly denounces cheap doctoring. For one to give advice and medicine for sixpence a visit is an evil and a wrong to the honorable portion of the profession, and it would be regarded as a disgrace to have anything to do with those who thus cheaply dispense advice and drugs. Still more does he decry the action of medical men engaging themselves with medical aid insurance societies. Such men are said by DR. MARTIN to be selling their birth-rights for a mess of pottage, and cannot have the smallest conception of the honorable character of their profession. Parties joining these societies are able to pay a medical man properly, and have no right to accept medical services for nothing or for insufficient remuneration. It is the duty therefore of the profession to stand together and see that they are not wronged in this respect. DR. MARTIN hopes that before long the powers of the Medical Council will be sufficiently enlarged to enable it to suppress all dishonorable practices in the profession.

A SUCCESSFUL ANGLO-INDIAN STUDENT.

LOYD ANDRIESEN is now a rising light in the medical profession. He is an Anglo-Indian and went to London to study medicine after gaining the Gilchrist Scholarship in India. He studied at University College, London, headed the list of the London University in the M. B. and M. S. degree, getting gold medals in both, and has now gained the highest medical degree—the M. D. of London. He has been appointed Superintendent of the Wakefield Lunatic Asylum in consequence of his special knowledge of mental diseases, and his writings in the London medical journals have already marked him out as a brilliant and promising physician. DR. ANDRIESEN'S career ought to inspire many of our Indian medical students to emulate his splendid example.

PAY HOSPITALS.

THE opposition to the attempt to introduce pay wards in the London Great Northern Central Hospital appears to be increasing. One member of the hospital staff has refused to submit to the system which expects the medical staff to give its services gratuitously in these wards, and a councillor who subscribed thirty guineas to the hospital threatens to ask for a refund of his subscription should the system of pay wards be permitted by the Committee, as he had given his money for the sick poor alone. We hope that the opposition will prove sufficiently strong to early abort the efforts of the Hospital Committee, and to thus deter other institutions from doing anything which will favor medical beneficence being taken undue advantage of.

NEW MEMBERS OF THE INDIAN MEDICAL ASSOCIATION.

WE have pleasure in publishing the names of the following gentlemen who have joined the Association since our last issue:—

- J. J. Brown, Asst. Surgeon, I. M. S., Station Hospital, Quetta.
- David Eikins, Asst. Surgeon, I. M. S., Station Hospital, Jullundur.
- C. S. Thirumadilawamy, Hospital Assistant, Civil Hospital, Madras.
- M. Ramamuni, C.M.S., Hospital Assistant, Civil Department, Port Blair.
- T. Ramchandram, C.M.S., Hospital Assistant, Civil Department, Port Blair.
- P. B. Sambuntha Mudelliar, Civil Apothecary, Conjeevaram.
- D. Robertson, Asst. Surgeon, I. M. S., Govt. House Dispensary, Ootacamund.
- Lakhmi Narain Chowdhuri, L.M.S., Asst. Surgeon, Hooshangabad, C. P.
- Jno. E. White, Asst. Surgeon, I. M. S., Station Hospital, Colaba, Bombay.
- George Morgan Dixon, L.M.S., Asst. Surgeon, Supdt. Sind Gang, Bahadipur, Karachi Dist.
- M. N. Mitra, L.M.S., Medical Officer, Dhalia Factory, Talup P. O., Dibrugarh.
- D. S. Ollenbach, Asst. Surgeon, I. M. S., Gunpowder Factory, Ichapur, 24-Pergunnahs.
- J. Fraser, Asst. Surgeon, I. M. S., Station Hospital, Nowshera, Punjab.
- Pandit Bishan Das, L.M.S., Asst. Surgeon, Chakwal, Punjab.

Medical men and women in all parts of India and Burma who desire to take a share in aiding the advancement of the Indian Medical Association are cordially requested to write to the Editor of the *Indian Medical Record*, and he will gladly send them blank membership forms and prospectuses. We are glad to find many willing volunteers.

EYE GLASSES OR OPERATION?

DR. R. H. SATTERLEE in a contemporary in whose columns he complains that the *phoria* craze has grown to such a pitch that conservative men meet with pitying smiles when they suggest that some cases of asthenopia *can* be relieved by proper glasses, asks "Is it time to call a halt?" If one eye sees as well as the other, and both are *equally* relieved of strain, the glasses are right, and in the majority of cases the muscles will adjust themselves; but unfortunately many victims are led to the altar of wholesale muscle-cutting, because many oculists are too indifferent about the *accurate* adjustment of glasses, and in many instances a weak myopic lens is given to the patient whether he be myopic or hyperopic, and this simply because the glass seems comfortable, and too little attention is paid to accurate refractive work.

'SUPPLY OF ANTI-TOXIN.

SIR JOSEPH LISTER has addressed a letter, calling upon the British public for subscriptions to enable the Institute of Preventive Medicine to manufacture on a large scale diphtheria anti-toxin, which he claims is harmless to either a healthy or a diphtheritic person, but is at the same time an almost infallible cure for the latter, if applied in the early stages of the disease. The prepared antidote will thus be placed within easy reach of every medical man, who will not only have a ready and effectual means of treating diphtheria, but also by subjecting his patient to no more pain than is occasioned by the hypodermic exhibition of morphia he will be able to render healthy persons attending on diphtheritic patients immune against an attack of the disease.

SHORT ITEMS.

In view of the fact, to which we recently called attention, that very large quantities of so-called "condensed milk," practically devoid of fat, are sold, it is of great importance to be able to rely on obtaining condensed milk containing its proper amount of fat, and not made with unwholesome sugars. We are able to recommend the ANGLO-SWISS COMPANY'S brands as being what they are represented to be, and as thoroughly reliable.

The first General Annual Meeting of the INDIAN MEDICAL ASSOCIATION took place at the Library and Office of the Association on Saturday 29th December 1894. Surgeon-Colonel Edward Lawrie presided. The ceremony of installing the Council, the address by the Chairman and the other parts of the programme were most successfully carried out. A full report will appear in our next number.

The undermentioned Military pupils having passed their final examination at the Grant Medical College, Bombay, are promoted to 3rd class Assistant Surgeons from the 17th of September 1894:—William Arthur Moore Wakeman, Michael Arthur Curry, Robert George Ives, Frederic Charles Henry Dady, Claude Cyril Kelly, and James Smith.

Before the introduction of vaccination, the mortality in Austria from small-pox was 62 per 100,000; in Prussia, 49. Since the introduction of vaccination, the mortality has been two cases in 700,000. In Germany, where re-vaccination is compulsory, the death rate is one patient in every 1,200,000.

Surgeon-Colonel Harvey, Inspector-General of Civil Hospitals, Bengal, has been granted furlough for eight months. Surgeon-Colonel O'C. Raye succeeds him in Civil Administrative charge of Bengal.

By a series of exhaustive experiments, Surgeon-Lieutenant R. H. Elliot, who is now acting as Professor of Biology at the Presidency College, Madras, is said to have proved that strychnine is no antidote to snake-poison.

At the last University Examination of Bombay Aloysius H. Fonseca, the son of Assistant Surgeon D. B. Fonseca of Kamptee, successfully passed the Intermediate Examination, in the 2nd class.

Consequent on Dr. Hooper's selection to succeed Sir Joseph Fayer, Dr. McDonagh goes from Allahabad to Lucknow, and Dr. O'Brien, of Benares, will be Civil Surgeon of Allahabad.

Surgeon-Colonel Cleghorn returns from leave and relieves Surgeon-Colonel Raye as Inspector-General, Civil Hospitals, Punjab.

At the distribution of honors to the successful students of the Lahore Medical College, His Honor the Lieutenant-Governor presided and gave away the prizes and certificates.

Messrs. Burroughs, Wellcome and Co. of Snow Hill Buildings, London, E. O., are prepared to supply antitoxin to the profession for the cure of diphtheria.

Dr. H. Wells, M.B., C.M., has been admitted to the Unconvenated Medical Service and posted, as Civil Surgeon, to the Ruby Mines, Mogok.

Surgeon Lieutenant-Colonel Geoffrey Hall has just successfully passed for a Fellowship of the Royal College of Surgeons of England.

Assistant Surgeon John E. White, D.G.M.C., I. M. S., resigns the service and enters on private practice in Bombay. We wish Dr. White every success.

Dr. J. A. Kelly, L.R.C.P. & S. Edin, Assistant Surgeon (Madras) and a Teacher in the Hyderabad Medical School (Deccan) has been selected F.O.S. London.

Dr. Chintaman Ramchandra Bakhle, of Bombay, has been admitted M.R.C.P. London, by examination.

We cordially wish all our readers a Happy New Year.

Current Medical Literature.

MEDICINE.

Lunatics who are Sane.

FRENZY, or great mental strain may so far unbalance mental equilibrium as to temporarily cause madness, which is not however so strongly or permanently developed as to justify the common practice of immuring the victim within the walls of a lunatic asylum where, if he is not already so, he may eventually be driven into a maniacal condition. And it frequently happens that to suit the cupidity or other ends of relations, &c., perfectly sane men and women are pounced upon and carried off to some asylum or another where they are compelled to endure all the miseries of companionship with those who are really mad. Not a very pleasant nor desirable picture of which instances can be easily multiplied, and are likely to continue to be so until the "Lunacy Laws" are revised and stringent measures adopted for the proper identification of those who are really insane, and for the easy access of duly qualified and State-appointed visitors and inspectors to the interior of these asylums for the purpose of unbiassedly watching the actual mental conditions of the victims within their walls and precincts with a view to the proper custody of those who are irretrievably insane and the release, under observation, of those whose mental aberration was only temporary and fugitive.

An unusual mode of transmitting Syphilis.

A MAN *et. 35*, was at the age of 28 infected with syphilis presenting a chancre, enlarged inguinal glands and mucous patches in the pharynx. He submitted to an energetic course of mercurial inunctions with apparent benefit; but syphilitic palmer psoriasis and other symptoms appearing in eight weeks' time he underwent a second inunction course followed up by Pot. Iod. Just prior to the marriage he took a third course of inunctions and then married a healthy girl by whom he had three healthy children and no miscarriages. The woman subsequently coming under the observation of SINGER with typical broad condylomata on either side of the labia majora, enlarged glands and syphilitic psoriasis on her neck, enquiry elicited that some months back there appeared on her husband's penis an herpetic ulcer and that was painless and soon disappeared, but it was from this time only that the symptoms of the wife dated; the only possible explanation is that the syphilitic poison had somewhere in the body of the husband (perhaps encapsulated within the prepuce) remained latent till set free from some unknown cause to occasion the vesicle that proved capable of transmitting the infection.

Treatment of Leucoplakia of the Tongue.

AFTER all other remedies had failed him in the treatment of a case where for *several* years a patient had suffered from exaggerated and very painful lingual leucoplakia probably consequent on a primary sore, (on the penis), contracted 13 years previously, but without sequelae, S ROSENBERG obtained a marvellously rapid cure by pencilling the tongue with a 20 per cent. solution of iodide of potassium. LEISTIKOW got very quick and successful results by several times a day (particularly after meals and just before going to bed) painting the patient's tongue by means of cotton-wool pledgets dipped in the following:—R *Terra silicea* 22.5 grs., *Resorcin* 45 grs., *Adipis* 3i, worked into a thick paste which dries on the part and penetrates deeply into the substance of the mucous membrane. The mouth must also be freely washed out with a solution of *boric acid* in water and this

hyperemia of the surface to which the ointment has been applied may be obtained by application of Peruvian balsam. Smoking and the use of pungent condiments must be strictly interdicted.

Pleuritis with Purulent Effusion cured by Aspiration.

A CASE of pleuritic effusion cured by aspiration is related by JAMES CARMICHAEL. The patient, a little girl of one year and nine months, had been ill for five weeks before admission with slight cough, and was becoming feeble and anemic. Physical signs of effusion on right side. The pleura was aspirated and twelve ounces of pus removed. Two days afterwards aspiration was again done, and three ounces of pus withdrawn. Five days later the process was repeated and four ounces removed. Again, three days later, three ounces were removed. It was now decided to drain, but, on incision, no pus escaped, and the wound was at once closed, and healing by first intention insured. Five days after incision aspiration was again tried, this time bringing two and one-half ounces of pus. No further aspirations required, the child making a complete recovery. Discharged well two months after admission. In all, five aspirations were done. Six months after leaving the hospital no difference could be detected in the physical signs on the two sides of the chest.—*Edin. Med. Jour.*

Inoculability of Cancer.

To solve the problem of the contagiousness of cancer GRATEA and LIENAU tried several experiments when they found that, with one exception, perfect union was obtained when they grafted fresh cancer into the skin, peritoneum and wall of the stomach; but when those organs that are most susceptible to cancer were inoculated with fresh cancer juice obtained by pounding or scraping primary or secondary tumours, the results were negative, and so were all attempts to transmit cancer from dog to dog, whether by grafting or by inoculation. Whence they infer (1) the parasitic nature of cancer has not been conclusively demonstrated; (2) grafting of cancer may be established in those persons chiefly who are predisposed to cancer; (3) the contagiousness direct or indirect of cancer is not proved.

Management of Measles.

THE danger in measles and whooping-cough lies in the complications, e.g., bronchitis and pneumonia, which may be coincident with the eruption on the skin and on the mucous surface of the bronchi and pulmonary vesicles—bronchopneumonia secondary upon measles or whooping-cough will occur either from lack of judicious treatment, or from the carelessness of the patient. Treatment should consist in keeping the patient in a warm room, and administering repeated full-doses of acetate of ammonia, which is eliminated by the lungs and destroys the microbes.—COHEN, in *Jour. de Méd. de Paris*.

Diagnosis of Infantile Scurvy.

BARLOW and NORTHEUP shewed that infantile scurvy was one of the results of faulty nutrition, and FRUITRIGHT finds that more cases are met with now than were encountered when breast feeding was more general, yet admits that scurvy does sometimes occur in breast-fed children, and especially in those who have been weaned too early and irregularly fed. As the disease has sometimes been confounded with acute rickets, rheumatism and infantile paralysis, he looks upon scurvy as the result of a faulty nutrition, leading to deficient alkalinity and a deviation of the normal constitution of the blood, and points out that though the bone and joint symptoms first appear in the lower extremities, they must always precede the mouth symptoms and hemorrhagic extravasations and that the three important symptoms were the bone lesions, the spongy condition of the gums, and the petechie also that under antiscorbutic scurvy generally ran a favorable course.

SURGERY.

Treatment of Prolapses of the Rectum.

DR. J. D. BRYANT says:—

1. That the proper performance of the physiological functions of the rectum contributes greatly to the advancement of rectal disease and to the sufferings of the afflicted.
2. That the complete vicarious discharge of the feces through an artificial anus located in the sigmoid flexure reduces the physiological demands on each structure of the rectum to a minimum.
3. That the lessening of the physiological requirements is commonly in direct proportion to the diminution of the fecal flow through the rectum.
4. That the cessation or lessening of the fecal discharge per rectum exercises a palliative and curative influence on diseases of the rectum.
5. That in certain cases of obstinate rectal prolapse the formation of a vicarious channel for fecal discharge is justifiable, both as a palliative and curative measure.
6. That the preliminary establishment of such a channel for the purpose of cleanliness and the prevention of infection is justifiable in many grave operations for prolapse of the rectum.
7. That the dangers attendant on the formation of an inguinal anus are much less than those invited by the contact of fecal discharges with large operative surfaces of the rectum.
8. That when cure takes place great care must be exercised thereafter, otherwise the prolapse will return.—*Mathews' Medical Quarterly*.

Subdural Hemorrhage.

DR. SHELTON HORSLEY records a case of this character which occurred in a man aged forty-three years. He had a syphilitic history and had been a hard drinker. One day in August, while sitting in a wagon he fell off, striking his left parietal eminence against a kerbstone. The wound was about an inch and a half long, but slight and not extending to the bone. He got up and seems to have had a slight convulsion affecting the left arm. He was then sent home, and at this time he was quite conscious. Half an hour later he suffered from general convulsions, and an hour after this was unconscious, with stertorous breathing. The head and eyes became turned to the left side and there was frequent spasm of the left arm. The patient gradually sank and died. Eight hours after the accident, at the necropsy, the blood vessels of the cortex were all engorged. There was found to be an irregularly shaped clot on the outer surface of the right temporo-sphenoidal lobe, covering a portion of the outer surface of the three temporo-sphenoidal convolutions. There was also a small clot on the anterior portion of the inner surface of the ascending frontal convolutions at its upper end. The walls of the blood vessels were much degenerated and therefore liable to rupture, and it is interesting to know that there was no fracture of bone and that the largest extravasation was found almost diametrically opposite to the point at which the skull had impinged on the kerbstone.—*Philadelphia Med. News*.

Trephining for Infantile Hemiplegia.

AN interesting case is described by Dr. ANGELL, of a patient, a child aged six years, suffering for infantile hemiplegia affecting the right side. The birth was difficult and prolonged, and the condition apparently arose at that time. The child had the usual condition of mal-development on the affected side,

it was mischievous, irritable, and dirty in habits, quite unable to use the right hand, and suffered from daily epileptiform attacks. Trephining was performed and a cyst punctured, but no attempt was made to remove it. With the exception of a severe convulsion and a high temperature a few days after the operation, the result of the pressure apparently of a too tight bandage, the patient's progress was excellent. The child was soon taught to be cleanly, began spontaneously to use the right hand, feebly and awkwardly, of course, and ceased to have convulsions. Six months after operation the condition was still improving. There had been no fits, and the mental improvement was maintained.—*Jour. Nervous and Mental Diseases.*

Treatment of Pelvic Abscess.

VOGEL maintains that a solitary pelvic abscess should be incised through the vagina, the operator discarding specula and other vaginal instruments, and trusting rather to his sense of touch to locate the prominent part of the abscess. For parametritis, pyocoele retro-uterina, or adhesive pyosalpinx, where the abscess cavity is cut off by pathological processes from the peritoneal cavity, a simple puncture suffices, but when the abscess cavity may not, with safety, be cut off from the peritoneal cavity, the edges of the sac and of the vaginal wound should be brought together by pressure forceps, which may be removed in 18 to 24 hours when the sac adheres to the vagina. Bleeding may be checked by the pressure forceps or by gauze tampons. A-I drain and a strip of gauze are passed into the sac, the gauze being removed in 36 hours and the I drain retained for 14 days or until the pus smells foetid or does not properly escape. The cavity being now and then washed out with Condy's fluid, the vaginal wound is kept open for several weeks by a spring wire drainage tube, especially when the patient insists on walking about.

Correction of High Myopia by Extraction of the Crystalline Lens.

T. WIDMARK has performed the operation suggested by FUKALA upon a servant-girl 23 years old, the degree of near-sightedness being 18 D.; visual acuity of the left eye, 0.1 to 0.2; of the right eye, 0.1. There were small atrophic spots on the choroid. The author had prescribed glasses (—13 D.) but she could only use them for a short time. Dissection was performed on the right eye, and the following day the crystalline lens was extracted, through a simple linear incision upward, about two millimetres inside the limbus corneae. V. A. 0.1, R. normal; twenty-four days later, V. A. 0.4 to 0.5, Hyperopia + 0.50. Myopia = 0. According to WIDMARK, the immediate danger after the operation is slight, but he cautions against its performance on both eyes, and believes it should only be attempted in cases of emergency.—*Hygia.*

Transplantation of the Human Cornea.

AT a recent meeting of the Vienna Society of Physicians, Professor FUCHS exhibited a case of transplantation of the human cornea. It is well known that Professor HIPPEL has succeeded in transplanting pieces of the cornea in four cases; but the pieces of cornea that he transplanted were small, whilst Professor FUCHS used flaps of from 4 to 5 mm. in diameter. Large pieces of the cornea, when transplanted, do not become opaque so soon as small ones. The pieces for transplantation used by Professor FUCHS in his case were taken from a human eye. Four weeks had elapsed at the time of exhibition since the operation had been performed, and the piece implanted was perfectly transparent, whilst in previous cases the opacity had commenced after the tenth day.

OBSTETRICS AND GYNECOLOGY.

Removal of Appendages: Fatal Haemoptysis.

QUENU cured a virgin, *et. 37*, for leucorrhoea and enjoined rest for two months. As she got worse instead of better, she was operated on and the appendages removed because the tubes were found fixed by adhesions, caseating, tuberculous and yellowish. She was doing well, but violent haemoptysis setting in on the third day, she died.

Dystocia from Tumour in Fetus.

MARSEN was present at an occipito-posterior presentation accouchement in which anaesthetics were employed as the child was easily expelled as far as the umbilicus; but its pelvis had stuck so fast that severe traction had to be used. The child died after birth, its pelvis was nearly 16 inches in circumference and on each gluteal region was a large congenital myxo sarcoma. KRASSOVSKY reported a somewhat similar case in which, however, the feet presented at beginning of labor and delivery, was considerably protracted by a large gluteal tumour on the foetus.

Fibroids and Conception, Pregnancy and Labor.

HOFMEIER denies that fibroid disease of the uterus where myoma or polypus, exerts any influence towards fertility or sterility, as these tumours seldom appear till late in sexual life, when the causes of fecundity or sterility must have influenced the woman long before the development of her fibroid. He thinks the best time for hysterectomy is a few weeks or months after delivery, and declares that unless the uterine cavity is rendered unfit to bear through the size and relations of the tumour, fibroids do not predispose to abortion, nor do they in any way interfere with gestation or with uterine contractions during labor.

Coils and Knots on the Funis.

As knots on the cord sometimes form after coils have been disengaged from the foetus during labor, LOVIOT urges that as the majority of births the head presents from the very first, the foetus can be freed from the coil, and knotting may be prevented and the loop undone by pulling it backwards in the direction whence it came. He thinks that knots being usually associated with long cords, the chance of danger from disengaging such a coil are trifling, and will not kill the foetus; but when the cord is a short one, and is constantly dragged upon a knot, would aggravate the evil by interfering with external rotation, or prematurely detaching the placenta, or inverting the uterus, or by killing the foetus.

An Ideal Napkin.

THIS is made from cheesecloth and cotton, both baked so as to be rendered sterile. A square is cut from the cheesecloth, nine by nine inches, folded over, and a piece of absorbent cotton of the same size (four and a half by nine inches) is placed between the folds. In this manner is prepared in the simplest possible way a compress available for receiving either the menstrual flow or the post-partum discharges, which is readily applied and which adheres closely when the subject is in the semi-recumbent position. Before applying afresh, the external genitals and the vulva should be bathed with warm water. It will not be amiss to give two warm vaginal douches, by means of a suitable syringe, every day. Should any odor be noticeable, the compress may be dusted with powdered boric acid. The addition of a little eucalyptol to the water for bathing adds materially to comfort.—*AMER. IN Medical Age.*

PHYSIOLOGY, PATHOLOGY AND BACTERIOLOGY.

The Physiology of the Spleen.

VULPIUS declares that histological study of the normal splenic tissue shows the possibility but not the certainty of the entrance of colorless cells into the circulation from the spleen: It is evident that the red cells undergo disintegration in the spleen, but there is no ground for assuming that they are formed in the spleen: Comparison of the blood of the splenic artery and vein shows no positive difference: In acute general anemia the spleen shows signs of increased activity: Removal of the organ causes a transient decrease in the number of red, or increase in the number of white, blood-cells: The thyroid gland has no vicarious relation to the spleen: Lymph-nodes and the bone-marrow acquire an increased blood-forming activity after extirpation of the spleen: Regeneration of blood is retarded after hæmorrhage in persons without spleens.

These conclusions, though contradicting certain accepted teachings, offer little that is new, but are of value in that they are based upon accurate scientific data, and corroborate much that has already been done. Unfortunately our knowledge of the physiology of the spleen is still left in a state of confusion.

The Relationship between Bovine and Human Tuberculosis.

SHERMAN and JAMKIN report the case of a boy, four years old, whose maternal grandfather had died of pulmonary tuberculosis, and whose nurse had about a year previously attended a daughter who also had died of pulmonary tuberculosis. The child had slight adenoid vegetations in the vault of the pharynx, and had suffered from two attacks of pneumonia, from both of which he had recovered entirely. When the boy came under observation, he presented a spastic gait, frequently stumbling. Classic symptoms of meningitis, believed to be of tuberculous origin, progressively developed and led to a fatal termination. Inoculation with tuberculin of three cows, from which was derived the mixed milk used by the patient, induced febrile reaction in two, and *post-mortem* examination in these demonstrated the existence of tuberculosis.—*N. Y. Med. Rec.*

The Bacterio Pathology of the Tooth-Pulp.

As the outcome of a study of the pulps of 250 diseased teeth, MILLER formulates the following conclusions: The infectious processes of the tooth-pulp are associated with but few exceptions, with mixed infection, cocci and bacilli being almost equally represented. Somewhat less frequently long, thin threads and spirals are found. Bacilli and threads with spores are also sometimes present, but not frequently. The microscopic examination of cover-glass preparations alone justifies the assumption that micrococci especially participate in the suppurative process. The bacteria find their way to the pulp principally through carious dentine, even a thin layer of which suffices to protect the pulp from infection. Infection of the pulp through the circulation, while conceivable, is scarcely capable of direct demonstration. The pulp is predisposed to infection by the action of the products formed in the carious dentine, such as acids and ptomaine. Forms of bacteria, particularly spirals, not capable of cultivation, play a prominent part in the production of disease of the pulp. A considerable number of cultivable bacilli have been found in connection with disease of the pulp; but, as a rule, they possess no special pathogenic activity. The typical pyogenic cocci, the staphylococcus pyogenes aureus and albus, and the streptococcus pyogenes, are but rarely found in pus in the pulp. On the other hand,

a number of cocci, particularly a closely related group that induce suppuration in mice, are found. In spite of careful search the presence of the pneumo-cocci could not be detected. The activity of cocci found in the pulp is increased by co-existence of putrefactive processes. A putrid condition of the pulp, whether the presence of bacteria in the body be demonstrable in pure culture or not, is always a dangerous source of infection. The putrefactive processes in the tooth-pulp are to be ascribed to various forms of bacteria. The putrefactive products are not always the same. In addition to gaseous substances there occur others whose nature is deserving of further study.—*Med. News.*

PUBLIC AND DOMESTIC HYGIENE AND JURISPRUDENCE.

Physical Culture in Unhealthy Schools.

THERE are one hundred and eighty sanitariously defective schools in Chicago, and the city spends about \$4,000 annually on an athletic overstrain far called "physical culture," whose chief purpose seems to be to provide "professional foreigners" of the ward-healer type with an occupation. The money wasted on this "physical culture" humbug could be advantageously employed in remedying the sanitary defects of a few schools.—*Med. Standard.*

How to Prevent the Spread of Venereal.

EVERY woman known to be a person of ill-fame should be duly licensed. She should be compelled to attend twice a week at some municipal building set aside for this purpose, there to undergo a proper medical examination by a physician appointed by the State, who should also enter her name, address and description in a book as a means of identification and endorse her license, such endorsement to hold good until next examination. If found diseased she should be sent to the nearest State hospital.

No male should be allowed to marry or to obtain a marriage license until he shall produce before the recorder a certificate from a physician stating that he is not contagious in a venereal sense, and that he has not contracted syphilis for three years past.

All wet nurses should, before entering on their duties, obtain a certificate of health from the certifying physicians.

All vaccination should be done solely by calf lymph.—*Pacific Med. Jour.*

A Condemned Bible.

AT the recent sessions of the Central Criminal Court, a prisoner was convicted of a crime which need not be specified; suffice it to say that a girl of the tender age of eleven years was, in consequence of that crime, infected with the virus of syphilis. The oath was administered to her in the customary way, whereupon MR. JUSTICE COLLINS very promptly and properly ordered the book to be destroyed. We have often insisted on the danger of the indiscriminate swearing of witnesses on the same volume of Holy Writ. It is matter for congratulation that the knowledge of this danger is reaching beyond the medical profession, and more so that so high a personage as one of Her Majesty's judges has publicly recognised the fact.—*Lancet.*

Imputation against a Medical Man: Apology and Withdrawal.

IT may be remembered that at the assizes held here last Easter, an action was brought by MISS GREY, a dress-maker at Waterloo, against DR. ALEXANDER MACKENZIE for damages, it being alleged that by his negligence in not discovering that her servant was suffering from small-pox the disease had spread through the house and ruined her business. The case ended in a verdict for the defendant, DR. MACKENZIE

being exonerated from any negligence. On 29th September last Miss GREY wrote a letter to a lady, in which she implied that Dr. MACKENZIE had committed perjury. The case was brought before the county magistrates on the 15th inst., and, counsel on each side having spoken, it was stated that Miss GREY had agreed in the frankest manner to withdraw and apologise for what she had written and to pay Dr. MACKENZIE a small indemnity in the shape of costs, which had been agreed upon. The presiding magistrate, while regretting what had happened, expressed the wish of the bench that the matter should be settled as proposed.—*B. M. J.*

:o:

THERAPEUTICS AND PHARMACOLOGY.

Turpentine in Incontinence of Urine.

THE unpleasant smell emitted by persons suffering from incontinence of urine can be conveniently covered, according to Dr. EMMINGHAUS, by means of ten-drop doses of turpentine administered in milk or water three times a day. This converts the smell of stale urine into an odour resembling that of violets, as is well-known to persons who have taken turpentine. The remedy is perfectly harmless in most cases, and has been given by PROFESSOR EMMINGHAUS for many weeks at a time without any inconvenience. It is, however, contra-indicated in ulcer of the stomach, gastric catarrh, and nephritis, and also some persons in whom turpentine tends to upset the digestive functions.—*Lancet.*

To Relieve the Thirst of Diabetics.

Pilocarpin may be administered in solution or in pill-form. The pills are best prepared by the addition of glycerine and gum arabic. Each contains $\frac{1}{10}$ grain of pilocarpin nitrate.

For the solution the following formulae is given:—

| | | |
|------------------------|-----|---------------------|
| R. Pilocarpin. nitrat. | ... | gr. $\frac{1}{4}$. |
| Spirit. vini dilut. | ... | ℥ss. |
| Aque | ... | 5j.—M. |

S.—The tongue is to be moistened with 5 or 6 drops on this solution four or five times daily.—*Nouv. Remèdes*, No. 11; *Corr.-bl. für Schenk. Aerzte*, 1894, No. 18.

On the administration of Chloral to Young Children.

DR. J. C. WILSON places much reliance on the soothing influence of chloral hydrate over the irritations of scarlet fever. As a rule, the drug is easy of administration and well borne by the stomach. I have found its acid after taste best masked by the administration in Anbergier's syrup of lactucarium diluted thus:—

| | | |
|-------------------------------|-----|----------|
| R. Chloralis | ... | gr. xxx. |
| Syrup. lactucarii (Anbergier) | ss | ... |
| Aque | ... | ℥ss.—M. |

Sig.: A teaspoonful in iced water every two, three or four hours.

The administration of nourishment immediately after the medicine is desirable. The sleep-inducing properties of the drug manifest themselves rapidly, but are not prolonged; therefore, its repetition at intervals of two or three hours is called for.

Cactus Grandiflora in Heart Disease.

IN two cases of Grave's disease, three of cardiac organic affections, and two of chronic parenchymatous nephritis MIKHAILOFF used the fluid extract and the tincture of cactus and found (1) a slight rise of arterial tension, disappearing on stopping the drug, (2) micturition increased in cases of Grave's disease but unaltered in cases of renal disease, (3) quick subsidence of dyspnoea and cardiac palpitation, (4) for permanent results prolonged exhibition and increasing doses of this remedy seem to be necessary.

CONTENTS.

A MEDICAL REGISTRATION ACT FOR INDIA. TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—With the advent of a new year and formation of the Indian Medical Association, our first duty to the profession is to make an effort to define the legal status of all qualified practitioners by the introduction of a Registration Act. The *Record* has often offered criticisms on the subject of such importance, and in the absence of any law protecting practitioners and their rights, the matter is not as simple as might be thought, while necessity for legislation in this direction may be expressed in the quotation of "*Tempora mutantur, nos et mutamur in illis.*"

By the Medical Act of 1858, 21 and 22, Vict. C. 90, amended in 1886, by 49 and 50 Vict. C. 48, no practitioner can maintain a professional claim in a law court unless he (or she) be duly registered, and this, despite the fact of possessing all the degrees or qualifications in the universe. Previous to the above Acts, physicians could not recover their fees, unless there was a special contract, whereby the patient, or some other person, promised and agreed to pay them:—(CHORLEY *vs.* BOLCOOT, 4 T. R. 317; VEITCH *vs.* RUSSELL, 8 Q. B. 928; Attorney General *vs.* College of Physicians, 80 L. J. C. 757.) It is presumed that anterior to 1858, the onus of proving a contract remained with the physician, and this difficulty was enhanced if the arrangement happened to be of a verbal nature, and the patient or other contracting party of an evil disposition. Now, however a physician can recover reasonable charges, &c., if duly registered (GIBBOR *vs.* BUDD, 32, L. J. Ex. 182). In the extreme presence of a patient repudiating liability as to contract, simple proof of attendance on the practitioner's side would be sufficient to constitute contract by implication to be good in law. An unqualified practitioner is not entitled to enforce a contract connected with the carrying on of a business, to carry on which lawfully, he needs to be registered (DAVIES *vs.* MAKUNA, L. R. 29, Chapter D. 586). But a qualified practitioner need not be registered at the time of rendering service, still he is compelled to register before he can sue if occasion occurs to necessitate him suing (LEEMAN *vs.* HOUSELY, L. J. Q. B. 22). As regards the Medical Register itself it is laid down.—"The Registrar of the General Medical Council is required to publish, every year, a correct list in alphabetical order, of the names of all persons qualified to practise, with their places of residence; such list to be called the Medical Register, and the absence of any name from such list will be evidence, in any court of law, that such person is not duly registered."

Protection is similarly afforded to Surgeons, Apothecaries, Accoucheurs and Dental Surgeons. Although by the Dentist's Act of 1878-41 and 42, Vict. C. 33, qualified medical practitioners are exempt from any liability or penalty.

That there is no obstruction before Government in formulating an Act for India is shewn under 31 Vict. C. 29, which indicates—"Every colonial legislature has full powers to make laws for enforcing registration within its jurisdiction, &c." Certain modifications are essential in

detailing a Medical Act for India, but the principles ought to be extended also to the constitution of chemists and druggists and others undertaking the sale of poisons and preparations of prescriptions. Fortunately it is repugnant to the feelings of a medical man to seek redress in a law court in connection with his profession, or to resort to such measures in any shape or form, however justifiable his reasons may be, but it has come within my knowledge, that defaulting or unscrupulous individuals have to be educated up towards realising that the medical profession invest both time and money in acquiring an honorable calling, and are equally entitled to be remunerated in the practice of their vocation. To demonstrate the impotency of a medical man's position in India, as to his legal status when suing, and the expression "reasonable charges," the patient pleaded through his lawyer non-liability on the ground of friendship, no contract, and exorbitant fees, to prove the latter a few other patients were cited as witnesses to shew they were usually charged less. The judge naturally disregarded the plea of friendship, and the doctor produced sufficient material to leave no doubt as to an implied contract (according to Addison), a reference was made to the High Court, the amount in dispute being only Rs. 75 the doctor got a decree, his fees being reduced by half. His partial success was due solely to being able to shew a contract of some sort or other and placed him in the position of a man practising before 1858, because he was not registered (though qualified to do so) and the High Court raised this technical objection.

The medical man in question qualified at home, and assuming there was no Act in India, he unconsciously neglected to register under the British Acts. I believe there are many Indian, Eurasian and European gentlemen who have similarly omitted to take this precaution, to their own apparent disadvantage, but what about those who qualify in India? If they are not permitted to legalize their Indian qualifications in London without qualifying at home also, what would their legal status in a law court be under similar conditions of the foregoing, and presuming they were allowed to register at home? Why should such a course be necessary when the expense and distance might be obviated by a Medical Act which already exists in Australia, Canada and other British colonies? The Bombay Medical Union, a few years back, petitioned for this reform, I think, making ample provision about indigenous practitioners who practise solely on the native system of medicine, but usurpers were to be dealt with rigorously and rightly so, as the English Act stipulates a summary conviction of £20 for falsely using the title of physician, surgeon, apothecary, or general practitioner. In India, these designations are used barefacedly because there is no recognised law, hindrance, or organization to institute proceedings for misrepresentation against those guilty of such a misdemeanour. Public policy demands legislative interference on their own behalf, as all their wants and requirements can be met by men fully qualified, without having to rely on persons as skilled in deception as they are unskilled in a profession in which they have no right, title or interest to practise so long as they make no effort to carry their

unsavory dealings into publicity. This class of men is far worse than the *vakil's* tout, who flounders at the expense of one pocket, while the former respects neither the pocket or life of their unfortunate dupes. In conclusion, I would beg of all members of the profession to exercise their influence and dignity in supporting the Indian Medical Association whose object it is to elevate the faculty in India by every constitutional means in its power to the advantage of younger members and particularly Indian graduates, who are starting life as medical men. Your profession is a noble one, and your dignity depends on your own dignified manner in which you practise it. It is only too common, yet a painful truth, that many members try to elevate themselves at the expense of their professional friends. Work in fair competition, but do nothing derogatory in thought or deed. If you succeed on such terms, it will always be a pleasure to know you were free from reproach both in your own and your friend's minds, always adopt the motto of "*Dum vicinus, vivamus*" to those entitled to compete with you.

Yours &c., ALF. McCABE DALLAS, L.M. Dub., L.R.C.P.I., &c.
KUMBHIR, 1st January 1895.

CINCHONA FEBRIFUGE IN TERTIAN AND QUARTAN AGUE.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—Quinine, though invaluable in the quotidian form of ague, is of little or no value when the ague assumes its tertian or quotidian forms. Then cinchona febrifuge becomes the remedy *par excellence*, as it generally breaks the fever paroxysm on the first day of its administration.

My procedure, while in medical charge of the taluka dispensaries at Modassa, Paranty and Samund, and during my present private practice, was to carefully enquire the approximate time that the fever paroxysm generally occurred (the afternoon usually) and six hours before the attack to give two four-grain pills of cinchona alkaloid. These pills were repeated every two hours till the fever came on, and it was seldom indeed that the ague, instead of being immediately checked, re-appeared on next turn-day.

I preferably give the pills on an empty stomach; but as the cinchona alkaloid, if taken alone, has a tendency to provoke headaches, giddiness, nausea and vomiting, I advise the patient (adult) to wash down the pills with 3 grains of carbonate of ammonia and 20 grains of bicarbonate of soda, dissolved in a wineglassful of water, so as to counteract the nausea, &c., and facilitate the action of the pills.

Yours, &c., JOSEPH BENJAMIN,
Medical Practitioner, Ahmedabad.

DIURETIN.

PANOWSKI prefers diuretin to digitalis whenever slowness of the pulse is a forerunner of uræmia, but does not recommend it in other cedematous conditions, although he lauds its value in valvular lesions and cardiac and renal affections where digitalis, camphor and caffeine have not given relief. He found it exert a tonic action on the cardiac muscles and a considerable increase of pressure in the vessels, which latter may probably be attributed to stimulation of the nerve centres, and thinks that the strongly-marked diuresis is really due to the increased pressure in the vasomotor system.

Government Medical Gazettes.

GOVERNMENT OF INDIA.

Surgn. Lieut. E. H. Sharmar, I. M. S. (Madras) to be offg. med. offr., 6th Infy, *vice* Surgn.-Lieut. G. Bidie, on furlough, 27th Nov.

Surgn.-Maj. P. D. Pank, I. M. S. (Beng.), Ready. Surgn. in Maywar, held temporary charge of the current duties of the office of Resdt. in Maywar, in addition to his other duties, from the 16th Sept. to the 1st Nov.

Surgn.-Capt. C. A. Johnston, I. M. S., (Madras), to be offg. med. offr., during the absence of Surgn.-Maj. C. Mallins, M.D., apptd. to office, as Depy. San'y. Commr., Madras, 6th Dec.

Surgn.-Maj. G. J. Kellis, I. M. S. (Beng.), med. offr., 4th Lancers, to be med. offr., *vice* Brig.-Surgn. Lieut.-Col. J. F. Sargent, of the 2nd Lancers, 1st Dec.

Surgn.-Capt. E. H. Wright, I. M. S. (Madras), to be offg. med. offr., 8th Infy., *vice* Surgn.-Maj. H. G. L. Wortabet, M.D., on furlough, 9th Nov.

Surgn.-Col. R. Harvey, M.D., D. S. O., Insp.-Genl. of Civil Hosps., Beng. leave (*p.a.*) for eight months.

Surgn. Lieut.-Col. William Henry Gregg to be Brig.-Surgn. Lieut.-Col., 20th June 1894.

Surgn. Lieut.-Col. Joseph Wilson, M.D. (Beng.) is permitted to retire from the service.

Asst. Surgn. George Murray Benjamin, I. M. S., Beng., is permitted to resign the service.

Hosp. Asst. Sobha Ram, of the Sudder Dispy., at Ulwar, held charge of the duties of the Agency Surgn. there in addition to his own, from the 9th July to the 31st Oct.

Hosp. Asst. Muhammad Nazir, of the Erinpura Irregular Force, availed himself of 15 days' leave on full pay from the 20th Nov.

From date of assuming charge Surgn.-Col. D. O'G. Raye, M.D. Offr. Insp.-Genl. of Civil Hosps., Punjab, is apptd. to office, as Insp.-Genl. of Civil Hosps., Beng., during the absence on leave of Surgn.-Col. R. Harvey, M.D., D. S. O.

Hosp. Asst. Chanda Singh, of the Abu Charitable Dispy., held charge of the Rajputana Agency Hosp. and of the Detachment, Erinpura Irregular Force, in addition to his own duties, from 1st Nov. to 14th Dec.

Hosp. Asst. Ashgar Ali Khan, of the Rajputana Agency Hosp. received medical charge of the Detachment, Erinpura Irregular Force at Abu, from Hosp. Asst. Chanda Singh, on the 16th Dec.

BENGAL GOVERNMENT.

Surgn.-Maj. R. H. Charles, Prof. of Surgical and Descriptive Anatomy, Med. Coll., Calcutta, and *ex-officio* Second Surgn. to the Coll. Hosp., acted as Prof. of Surgery, Med. Coll. Calcutta, and *ex-officio* First Surgn. to the Coll. Hosp., from 16th Oct. to 1st Nov., *vice* Surgn. Lieut.-Col. J. O'Brien, on leave.

Surgn.-Capt. F. O'Kinealy, Resdt. Med. Offr., Med. Coll. acted as Prof. of Surgical and Descriptive Anatomy, Med. Coll., and *ex-officio* Second Surgn. to the Coll. Hosp., *vice* Surgn.-Maj. E. H. Charles.

Dr. P. R. Hay Jagannadham, Offg. Civil Med. Offr. of Khulna, is allowed priv. leave for three days in extension.

Surgn. Lieut.-Col. C. J. W. Meadown, Civil Surgn. of Murshidabad, to act as Civil Surgn. of Burdwan, *vice* Surgn. Lieut.-Col. G. Price.

Surgn.-Capt. G. Jameson, Offg. Civil Surgn. of Rajshahi, to act as Civil Surgn. of Malda.

Surgn.-Capt. W. J. Buchanan to do genl. duty at the Preddy, on being relieved of duties as Offg. Civil Surgn. of Champaran.

Surgn.-Capt. T. Grainger, Civil Surgn. of Khulna, to act as Civil Surgn. of Naskibail, *vice* Dr. C. Banks.

Asst. Surgn. Kali Nath Banerjee leave for one month in extension.

Asst. Surgn. Khitrode Chandra Chowdhuri did superny. duty at the Campbell Hosp. from 5th to 24th Nov.

Asst. Surgn. Khitrode Chandra Chowdhuri to do the duties of Mr. Brittain at the Campbell Hosp. during his absence on leave.

Asst. Surgn. Kunja Behary Nuzid, of the Cox's Bazar sub-lev. and dispy., is apptd. to the dispy. at Jamul, Monghyr Dist., *vice* Asst. Surgn. Gopal Chunder Mukerjee, transferred.

Asst. Surgn. Annada Prasad Bhattacharya, at the Med. Coll. Hosp., is apptd. to the Cox's Bazar Dispy., Chittagong Dist., *vice* Asst. Surgn. Kunja Behary Nuzid, transferred.

Surgn. Lieut.-Col. B. Bosh made over Bandipore Jail to Brig.-Surgn. Lieut.-Col. F. C. Nicholson, 2nd Dec.

Surgn.-Capt. W. J. Buchanan made over Motihari Jail to Surgn.-Lieut.-Col. E. Byvill, 8th Dec.

Surgn.-Capt. R. Bird made over Dacca Central Jail to Surgn.-Lieut.-Col. E. G. Russell, 18th Dec.

Surgn.-Col. R. Harvey, M.D., D. S. O., Insp.-Genl. of Civil Hosps., Beng., leave (*p.a.*) for eight months.

Surgn. Lieut.-Col. William Henry Gregg to be Brig.-Surgn. Lieut.-Col., 20th June 1894.

Surgn. Lieut.-Col. Joseph Wilson, M.D., (Beng.) is permitted to retire from the service.

PUNJAB GOVERNMENT.

Surgn.-Capt. A. Coleman, Supdt. of the Montgomery Central Jail, priv. leave for 2 months and 27 days, 2nd Nov.

Surgn.-Maj. D. St. J. D. Grant resumed duties as Professor in the Lahore Med. College and Chemical Examr. to the Govt. of Punjab, 23rd Nov., relieving Surgn.-Capt. C. H. Bedford, whose services have been replaced at the disposal of the Govt. of India.

Brig.-Surgn. Lieut.-Col. Maasy, Civil Surgn., Murree, priv. leave for one month, 1st Dec.

Asst.-Surgn. W. Clark, Lawrence Memorial Asylum, Murree, to office, as Civil Surgn. of Murree, in addition to his own duties, 1st Dec., *vice* Brig.-Surgn. Lieut.-Col. G. Maasy, on leave.

Hosp. Asst. Sunder Singh, from the Sayadwala to the Kamalia Dispy., Montgomery Dist., 22nd Nov.

Hosp. Asst. Sahadat Ali, Kamalia Dispy., Montgomery Dist. three months' priv. leave, 27th Oct.

Hosp. Asst. Ghasia Mal resumed charge of the Mong Dispy., Gujrat Dist., 17th Nov., relieving Hosp. Asst. Khair-ud-din, apptd. to genl. duty at Gujrat, 24th Nov.

Hosp. Asst. Rahim-ud-din, Jail and Police Hosps., Dharmasala, three months' priv. leave, and was relieved on the 23rd Nov. by Hosp. Asst. Muhammad Jan, Dharmasala Sadar Dispy.

Hosp. Asst. Barkat Ali, Phillour Dispy., Jullundur Dist., three months' priv. leave, and was relieved on the 24th Nov. by Hosp. Asst. Kamal-ud-din, transferred from the Jullundur Civil Hosp.

Hosp. Asst. Bisanada Ram resumed charge of Shorkot Dispy., Jhang Dist., 5th Dec., relieving Hosp. Asst. Fazl Iahi, apptd. to duty in the Jhang Dist.

Surgn.-Capt. J. S. Lumsden made over Dera Ismail Khan Jail to Surgn.-Maj. J. Shearer, 1st Nov.

Surgn.-Maj. J. A. Neils, made over Abbottabad Jail to Surgn.-Col. J. T. B. Bookey, 15th Nov.

Surgn.-Maj. S. E. Bigger made over Kohat Jail to Surgn.-Capt. B. J. Shingh, 15th Nov.

Surgn.-Lieut.-Col. J. T. B. Bookey made over Abbottabad Jail to Surgn.-Capt. F. H. Ozard, 29th Nov.

Surgn.-Capt. B. J. Singh made over Kohat Jail to Surgn.-Capt. A. T. Bown, 4th Dec.

Surgn.-Maj. J. Shearer made over Dera Ismail Khan Jail to Surgn.-Maj. G. S. Griffiths, 6th Dec.

Surgn.-Maj. G. S. Griffiths assumed charge of the civil med. duties of Dera Ismail Khan on the 6th Dec., relieving Surgn.-Maj. J. Shearer.

Surgn.-Capt. A. T. Bown assumed charge of the civil med. duties of Kohat on the 4th Dec., relieving Surgn.-Capt. B. J. Shingh.

MADRAS GOVERNMENT.

Surgn.-Maj. Clement Mallins, M.D., to act as Inspr. of Vaccination and Depy. San'y. Commr., Madras, during the absence of Surgn.-Capt. W. B. Bauman on leave.

Surgn.-Lieut.-Col. T. C. H. Spencer, I. M. S. Madras, has been permitted to retire from the service, 31st Dec. 1894.

Surgn.-Capt. D. Simpson, further extension of leave on med. certificate for two months.

Surgn.-Maj. W. H. Neilson, M.B., I. M. S. (Madras), Med. Officer of the Erinpura Irregular Force, to office, as Agency Surgn., Alwar, from date of assuming charge, and during the absence on furlough of Surgn.-Maj. A. S. Faulkner.

Surgn.-Capt. C. F. Fearnside, Acting Dist. Medical and San'y. Officer, Cuddapah, priv. leave for one month, 10th Dec.

BOMBAY GOVERNMENT.

The following promotions are made in the Apoth. Branch of the Sub. Med. Dept.—

Sub-Ast. Apoth. Nicholas Martin, to be Asst. Apoth., 2nd grade, 14th Jan. 1893, *vice* Mr. Joseph DeMonte, deceased.

Sub-Ast. Apoth. J. M. Nunes, to be Asst. Apoth., 2nd grade, 3rd June 1893, *vice* Asst. Apoth. C. Hudson, promoted.

Sub-Ast. Apoth. S. Simoes, to be Apoth. 2nd grade, 4th March 1894, *vice* Asst. Apoth. S. Carvalho, promoted.

Sub-Ast. Apoth. L. D'Souza, to be Asst. Apoth., 2nd grade, 8th March 1894, *vice* H. T. Corke, resigned.

Sub-Ast. Apoth. Denis Crumly, to be Asst. Apoth., 2nd grade, 12th March 1894, *vice* Asst. Apoth. Sorabji Nusservanji, promoted.

Sub-Ast. Apoth. H. F. G. Kinsley, to be Asst. Apoth., 2nd grade, 18th April 1894, *vice* Asst. Apoth. A. G. Cazalet, promoted.

The following promotions are made among Asst. Surgns. of the Indian Sub. Med. Dept.—

Asst. Surgn. John Alexander Judd, from 2nd class to the 1st class, 24th June 1894, *vice* L. Soares, deceased.

Asst. Surgn. L. A. D'Souza from 3rd class, to the 2nd class, 24th June 1894, *vice* J. A. Judd, promoted.

Asst. Surgn. Joaquim Emanuel D'Souza, from 2nd class to the 1st class, 6th July 1894, *vice* C. H. Bell, deceased.

Asst. Surgn. Arthur Victor Marshall King, from 3rd class, to the 2nd class, 6th July 1894, *vice* J. E. D'Souza, promoted.

Asst. Surgn. George Archibald Deane, from 3rd class, to the 2nd class, 7th July 1894, *vice* W. C. A. Desmire, deceased.

Asst. Surgn. Claude Benjamin Pollock, from 3rd class, to the 2nd class, 24th Sept., *vice* Lieut. Peter Barrett, dismissed.

Surgn. Lieut.-Col. F. O. Barker, M.D., F.R.C.S.I., on relief by Brig.-Surgn. Lieut.-Col. S. O. B. Banks, F.R.C.S.I., to resume charge as Med. Offr. to the Kathiawar Political Agency and in charge of the West Hosp., Rajkot.

Surgn.-Capt. H. Herbert, F.R.C.S., on relief by Surgn. Lieut.-Col. Barker, to resume charge of appointment as Civil Surgn., Kaira.

Surgn.-Capt. J. L. T. Jones, M.B., on relief by Surgn.-Capt. Herbert, to act as Civil Surgn., Broach, pending further orders.

Asst. Surgn., Peter Barretto, 1st class, to be Senr. Asst. Surgn. with the hon. rank of Surgn.-Lieut., 18th April.

Asst. Surgn. N. K. Kallianwalla, L.M. & S., to act as Demonstrator of Anatomy, Grant Med. Coll., 1st Nov., *vice* Asst. Surgn. Anna Moreshwar Kunte on leave.

Brig.-Surgn. Lieut.-Col. C. T. Peters, M.B., acting Civil Surgn., Satara, priv. leave for two months.

Surgn.-Maj. R. Manser, M.D., acting Senr. Med. Offr., J. J. Hosp., furlough from 22nd Dec. 1894 to 15th Nov. 1895.

Asst. Surgn. Phiroosha Palanji Mullin, L.M. & S., to act as Civil Surgn., Ratnagiri, until relieved by Surgn.-Maj. J. Crimmin, V.C.

Surgn.-Maj. R. W. S. Lyons, M.D., to act as First Physician, J. J. Hosp., *vice* Surgn.-Maj. R. Manser, M.D.

Asst. Surgn. Abdul Ghaani Hakim, L.M., is promoted from the 2nd to the 1st class of Asst. Surgns., 19th Nov.

Asst. Surgn. Erachji Sheriarji Bharucha, L.M. & S., has been apptd. sub. *pro tem* Asst. to the Med. Offr., Kathiawar Political Agency, and in charge of the West Hosp., Rajkot, *vice* Asst. Surgn. F. T. Davar.

Surgn.-Maj. F. F. MacCartie, M.B., B.C.M. (Dub.), on return from furlough to take up his appointment as Health Offr. of the Port of Bombay.

Surgn.-Maj. J. Crimmin, V.C., on relief, to take up his appointment of Civil Surgn., Ratnagiri.

Asst. Surgn. Darabhai Edalji Kothavala, L.M. & S., to act as a Teacher in the B. J. Med. School, Ahmedabad, 29th Nov., *vice* Asst. Surgn. N. K. Kalyanavala, L.M. & S., transferred to Bombay.

Asst. Surgn. Jivram Allimchand Lalvani, L.M. & S., to act as Teacher of Surgery and Midwifery at the Med. School, Hyderabad, 29th Nov., *vice* Asst. Surgn. John Eugene Bocarro L.M. & S., granted leave.

CENTRAL PROVINCES GOVERNMENT.

Surgn.-Capt. C. N. Penney and S. A. C. Dhillon respectively made over and assumed charge of the office of Civil Surgn., Chanda, 5th Dec.

Civil Hosp. Asst. Syed Abdul Asia, of the Civil Station Disp., Nagpur, is transferred to the Murwara Branch Disp., Jabulpore Dist., *vice* Civil Hosp. Asst. Ram Krishna Appaji, appointed to the Civil Station Disp., Nagpur.

Civil Hosp. Asst. Syed Ballar, on return from leave, to do duty under orders of the Civil Surgn., Raipur.

Civil Hosp. Asst. Ram Krishna Appaji, on return from leave, to do duty under orders of the Civil Surgn., Jabulpore, 17th May.

Civil Hosp. Asst. Baghunath Tukaram, of the Raj-Nandgaon State Disp., is appointed to the Central Jail Hosp., Jabulpore, *vice* Civil Hosp. Asst. Gokul Pershad directed to do duty under orders of the Civil Surgn., Jabulpore.

Civil Hosp. Asst. Abdul Ramak Khan, doing duty under orders of the Civil Surgn., Chanda, is appointed to the Mul Branch Disp., Chanda Dist., *vice* Civil Hosp. Asst. Shait Karim Bux, who retires from the service.

Three months' priv. leave is granted to Civil Hosp. Asst. Abdul Karim, attached to the Deoli Branch Disp., Wardha Dist., 8th Dec.

Civil Hosp. Asst. Ujagar Pershad, doing duty under orders of the Civil Surgn., Nagpur, is temply. posted to the Deoli Branch Disp., Wardha Dist., *vice* Civil Hosp. Asst. Abdul Karim.

Civil Hosp. Asst. Luchman Pershad, doing duty under orders of the Civil Surgn., Nagpur, is directed to do duty under orders of the Civil Surgn., Narsinghpur.

Two months and four days' priv. leave was granted to Civil Hosp. Asst. Ashfaq Hussain, of the Garhakota Disp., Saugor Dist., 7th Oct. to 10th Dec.

Civil Hosp. Asst. Surji Rao, doing duty under orders of the Civil Surgn., Saugor, did duty at the Garhakota Branch Disp., from the 1st Nov. till the 10th Dec.

Relieved by Civil Hosp. Asst. Ashfaq Hussain, Civil Hosp. Asst. Surji Rao is directed to do duty under orders of the Civil Surgn., Saugor.

Six months' sick leave is granted to Civil Hosp. Asst. Ashmat Ali, of the Jail and Police Hosp., Bhandara, 15th Oct.

Civil Hosp. Asst. Rama Gail, doing duty under orders of the Civil Surgn., Balaghat, is appointed to the Jail and Police Hosp., Bhandara.

Civil Hosp. Asst. Jairam Daulat, of the Main Disp., Bhandara, was directed to do duty at the Jail and Police Hosp., Bhandara, in addition to his own duties, till he was relieved by Civil Hosp. Asst. Rama Gail.

Relieved by Asst. Surgn. Rajoni Kant Das Gupta, on return from leave, Civil Hosp. Asst. Gunga Pershad Singh, temply. attached to the Main Disp., Bilaspur, is directed to do duty under orders of the Civil Surgn., Bilaspur.

N.-W. P. AND OUDH GOVERNMENT.

Asst. Surgn. Binode Bihari Ghose, in charge of the Chander Disp., Mirzapur Dist., priv. leave for ninety days, 7th Jan. 1895.

Hosp. Asst. Muhammad Boshan, of the reserve list, to the charge of the Husalnabad Disp., Lucknow, *vice* Asst. Surgn. Ghulam Mustafa, granted priv. leave.

The undermentioned Asst. Surgns. of the Provincial Staff of the N.-W. P. and Oudh, having successfully passed their septennial professional exam., are promoted to the first grade from the dates specified against their names—Jwala Prasad, 1st Nov., and Bihari Krishna Rana, M.A., 3th July.

BURMA GOVERNMENT.

Mr. H. Wells, M.B., C.M., who has been temply. admitted to the Unconvenanted Med. Service, is posted as Civil Surgn. of the Buby Mines, *vice* Asst. Surgn. F. Bradley, transferred from Mogok to Tiddim to be Civil Surgn.

Surgn.-Capt. J. W. Wolfe, leave extended by two months and 12 days.

Surgn.-Capt. R. H. Caator, from Yamethin to Rangoon to offic. as Secy. to the Insptr.-Genl. of Jails, with civil med. administration, *vice* Surgn.-Capt. J. W. Wolfe.

Surgn.-Capt. T. W. Stewart is transferred from Meiktila to Yamethin as Civil Surgn.

Asst. Surgn. R. H. Nailer, on return from priv. leave, is posted to Pakokku as Civil Surgn. *vice* Asst.-Surgn. J. T. Weston, on leave.

Privilege leave for 52 days is granted to Asst.-Surgn. J. T. Weston, 11th Nov.

Ast. Surg. F. X. de Attalides, on three months' priv. leave, made over, and Mr. H. J. Augustine assumed charge of the Civil Surgeoncy, Myitkyina, 23rd Oct.

Hosp. Asst. Jan Mahomed left Civil Hosp., Kindat, and assumed charge of the Police Hosp., Mandalay, 15th Nov.

Hosp. Asst. D. P. deSouza assumed charge of the Police Hosp., Bhamo, 24th Oct.

Hosp. Asst. Prem Dass left Police Hosp., Bhamo, and assumed charge of the Outpost Hosp., Sikaw, Bhamo Dist., 17th Nov.

Hosp. Asst. Abius Sattar, on three months' priv. leave, left Police Hosp., Rangoon, 27th Nov.

Hosp. Asst. Shaik Abdulla assumed, as an additional duty, charge of the Police Hosp., Rangoon, 27th Nov. *vice* Hosp. Asst. Abius Sattar.

Hosp. Asst. S. Paul, on return from leave, assumed charge of the Civil and Police Hosps., Sagaing, 1st Dec.

Hosp. Asst. S. Paul assumed, as an additional duty, charge of the Lock-up, Sagaing, 1st Dec., *vice* Hosp. Asst. S. Chinnaswamy Naidu.

Hosp. Asst. Ahmed Khan, on return from leave, assumed charge of the Police Hosp., Mandalay, 1st Dec.

Hosp. Asst. T. J. Padmanatha made over, and Hosp. Asst. N. Vijayaraghawa Moodelly assumed, in addition to his own duties, charge of the Civil Dispy., Loikaw, Southern Shan States, 1st Oct.

Hosp. Asst. Badha Nath Sing left Jail Hosp., Mandalay, and assumed charge of the Police Hosp., Bhamo, 17th Oct.

Hosp. Asst. Badha Nath Singh, on transfer to Mogaung, left Police Hosp., Bhamo, 20th Oct.

Hosp. Asst. Raghunatha Singha left Police Hosp., Bhamo, and assumed charge of Mogaung, as a reserve for escort duty, 16th Nov.

Hosp. Asst. Maula Baksh left Police Hosp., Monywa, and assumed charge of the Outpost Hosp., Zeitlaung, Lower Chindwin Dist., 24th Nov.

Hosp. Asst. M. S. Munisawmy Naidu is granted an extension of leave for three days, 12th Nov.

Hosp. Asst. A. Koihaudaramasawmy Naidu left Outpost Hosp., Mawlu, and assumed charge of the Police Hosp., Katha, 24th Nov.

Hosp. Asst. T. J. Venkatchellam Naidu left Jail Hosp., Mandalay, and assumed charge of the Ry. Dispy., Pynmaua, 30th Nov.

Hosp. Asst. Rajab Ali, extension of six months' leave, 1st Nov.

Hosp. Asst. S. Chinnasawmy Naidu left Civil and Police Hosp., Sagaing, and assumed charge of the Civil Hosp., Pynmaua, 5th Dec.

Hosp. Asst. S. Chinnasawmy Naidu assumed as an additional duty charge of the Police Hosp., Pynmaua, 5th Dec., *vice* Hosp. Asst. R. S. Deshmookha.

Hosp. Asst. Ahmed Khan left Police Hosp. and assumed charge of the Jail Hosp., Mandalay, 4th Dec.

Hosp. Asst. P. Govindarajoo Moodelly left Police Hosp., Minbu, and assumed charge of the Civil Dispy., Pakokku, 26th Nov.

Hosp. Asst. Heeml Shariat assumed charge of the Police Hosp., Momeik, Ruby Mines Dist., 29th Nov.

Hosp. Asst. Syed Abdul Gunny left Ry. Dispy., Pynmaua, and assumed charge of the Genl. Hosp., Mandalay, 3rd Dec.

G. O. C. C.

The undermentioned passed the Lower Standard in Pushtu, 28th Sept. 1894:—Surgn.-Capt. E. Wilkinson and Surgn.-Lieut. H. G. Melville, I. M. S.

Native Mily. pupil Kanhaiya Lal having passed his final exam. is admitted into the service as Sub. Hosp. Asst., 1st Oct.

Surgn.-Lieut.-Col. F. W. Wright, D.S.O., from the med. charge of the 43rd Gurkha Rifles, to the charge of the 6th Beng. Infy., *vice* Surgn.-Capt. R. C. Macwatt.

Surgn.-Lieut. Col. W. A. Murphy, D.S.O., from the med. charge of the 2nd Battn., 2nd Gurkha Rifles, to the charge of the 1st Battn., 2nd Gurkha Rifles, *vice* Surgn.-Lieut.-Col. A. M.M. Paterson.

Surgn.-Maj. A. Duncan, from the med. charge of the Corps of Guides and offg. med. charge of the 1st Battn., 3rd Gurkha Rifles, to the charge of the 2nd Battn., 2nd Gurkha Rifles, *vice* Surgn.-Lieut.-Col. W. B. Murphy, D.S.O.

Surgn.-Lieut.-Col. J. T. B. Bookay, from the med. charge of the 6th Punjab Infy. to the offg. charge of the 1st Battn., 5th Gurkha Rifles, *vice* Surgn.-Maj. J. A. Nelis.

Surgn.-Capt. F. H. Burson-Brown, to the med. charge of the 43rd Gurkha Rifles, *vice* Surgn.-Lieut. Col. F. W. Wright.

The undermentioned passed the Higher Standard in Pushtu on the 29th and 30th Oct. 1894:—Surgn.-Capt. H. B. Cleveland, I. M. S., and Asst.-Surgns. B. T. Rodgers and C. J. Fox.

ASSAM GOVERNMENT.

Sick leave for three months is granted to Hosp. Asst. Kailas Chandra Das (II), in charge of Jagi Dispy., Nowgong Dist., 5th Dec.

Hosp. Asst. Afzal Husain, a superny. in the Nowgong Dist., is appointed to the Jagi Dispy., 5th Dec., *vice* Hosp. Asst. Kailas Chandra Das (II).

The services of Surgn.-Capt. C. Duer, M.B., F.R.C.S., I.M.S. (Beng.), Offg. Civil Surgn., Goalpara, are placed at the disposal of the Govt of India, Home Dept.

Asst. Surgn. Pramatha Nath Banerji is apptd. temply. to hold civil med. charge of the Naga Hills Dist., in addition to his own duties, 6th Dec.

Hosp. Asst. Bipin Behari Datta, a superny. in the Lakhimpur Dist., is apptd. to the med. charge of the Bomjor outpost in that dist., 18th Oct.

DOMESTIC OCCURRENCE.

BIRTH.

GRAYFOOT.—On 14th December at Bandora Hill, Bombay the wife of Surgn.-Capt. B. B. Grayfoot, I.M.S., of a daughter

ACKNOWLEDGMENTS.

A REVIEW OF INDIAN PHARMACOLOGY.*

By RAI BAHADUR KANNY LALL DEY, C.I.M., F.C.S., G.M.C.B.

Being the Address of the President of the Section of Pharmacology at the Indian Medical Congress.

The immortal DARWIN concluded one of his most exhaustive monographs with the words:—"We only see how little has been made out in comparison with what remains unexplained and unknown." This is exactly my feeling to-day in attempting to place before you a brief review of the subject which I have made a study for more than forty years.

I am fully conscious of the responsibility attached to the office to which you have done me the honor to elect me, and I trust that you may not be disappointed in my fulfilment of these responsibilities. I am becoming more and more reconciled to the fact that advancing age constrains me to leave this legacy of work undone to younger and abler men, but I shall endeavour in the time at my disposal to lay before you a sketch of the Progress of Pharmacology in India with some suggestions for the possibilities of its future.

It may not be unprofitable to glance for a moment at the ancient *Sanskrit Materia Medica* of a time long preceding the advent even of Mohammedanism into India over seven centuries ago. I have quite lately found great pleasure and no small instruction in a research into the old Sanskrit works dealing with the classification of vegetables and the utilisation of their parts in medicine as practised by the physicians of India of the Puranic era some thirteen centuries ago. The elaborate directions for the collection of drugs and their subsequent manipulation is, strange as it may seem to European minds at least, not by any means unworthy of the methods of to-day, and you will perhaps be astonished to learn, as I was to find, that some of the mistakes of the most ancient of these Sanskrit writings survive in some of the best books treating of the indigenous drugs of India at the present time. They shew the great progress which the ancient Hindus had made in the healing art. Minute instructions were given on every conceivable point, such as the gathering of herbs, preparation of medicines, etc. Annual plants were to be collected before the ripening of the seed, biennials in the spring, and perennials in the autumn: twigs were to be of the current year's growth: the roots to be collected in the cold season: the leaves in the hot season and the barks and woods in the rains. There were no fewer than twenty-six forms of medicine, including powders, extracts and boluses, decoctions and infusions in water and milk, syrups, expressions, distillations, fermentations, and medicated oils, many of them crude enough in their exhibition, but wonderfully efficacious in the respective ailments for which they were designed.

Not, however, until the quickening influence of British supremacy had been fully established in India was any notable attempt made of which there is any record, to improve or to augment what was already known of the medicinal resources of this country.

SIR WILLIAM JONES' "Botanical Observations on Select Indian Plants," was one of the earliest contributions in this direction: JONAS FLAMINO's "Catalogue of Medicinal Plants" (1810); ANSLEY's "Materia Medica of Hindustan" (1818 and 1826); ROXBOROUGH's "Flora Indica" in 1820, and the labors of WALLICH, BOYLE, and later of DR. F. J. MOUTAT and F. N. MACNAMARA and other ardent botanists did much towards resolving the chaos in which they found the vast mass of material at their disposal into some degree of scientific arrangement.

The gradual progress of Indian Pharmacology, the widening and deepening of its influence, and its possibilities in contributing to the health and consequent prosperity of this vast Empire have been in complete sympathy with the gradual development of commerce, medicine and science in this country. Clear of the mythology and superstition from which it evolved, not unlike the medical science of Europe, but which lingers still in India, the science has in some measure at least demonstrated the marvellously liberal provision of curative and remedial agents within the reach of the teeming millions of this Empire. Following O'SHAUGHNESSY's *Bengal Pharmacopœia* (1844), the publication of the *Pharmacopœia of India* (1868) under the editorship of DR. WARING, signalled a new epoch in establishing the value of indigenous medicinal products. The more important were stamped with some measure of official recognition, a preliminary step to the ultimate adoption of several in the *British Pharmacopœia*, a distinction of which many more—as I shall hope to shew—are equally worthy. DR. MOORE'S SHERIFF's "Supplement to the Pharmacopœia" published in the following year added very materially to the usefulness of that work, and DR. U. C. DUTT's translation of "Sanskrit Materia Medica" enriched this department of medical science in no inconsiderable degree. The painstaking labors of FLOCKNER and HAMBURY, as embodied in the *Pharmacographia*, were of incalculable value in recording some most important material relating to the medicinal products indigenous to British India. Among recent authors the work of the late lamented DYMOCK has been perhaps the most valuable. His "*Materia Medica of Western India*" (1883) was a most careful compilation, while his later work, *Pharmacographia Indica*, in joint authorship with WARREN and HOPPER, is an admirable emulation of its almost perfect prototype.

The comprehensive "Dictionary of the Economic Products of India" by my honorable colleague in the Presidency of this section of the Indian Medical Congress, DR. GEORGE WATT, combines a condensation of the literature of the subject with all the information it has been possible to secure through official and other sources. MR. T. N. MUKERJI, of the Imperial Museum, Calcutta, has by the genuineness of his work in this department of science and his painstaking attention to details, come to be recognised as an authority on all matters relating to the indigenous drugs of India. Another earnest worker in this department at present is Surgeon-Captain B. D. BASU. This science is also greatly indebted to MR. THOMAS CHRISTY, F.L.S., London, for his unremitting exertion to discover the value of and to introduce new drugs to the commercial world.

* Sent by author for publication in Record.

International Exhibitions in different parts of the world, and the invitations to the Indian Government to prepare exhibits, infused fresh impetus into the somewhat commonplace researches into the medicinal resources of this country.

Thus attempts have been made to separate the wheat from the tares. The literature on the subject is voluminous, tending even in the best and most recent works towards reproduction and the repetition, as I have already pointed out, of statements that should long ago have been relegated to the oblivion whence they originated. In a new edition of my own little work (published originally in 1867), on the "Indigenous Drugs of India," now in the press, the advance sheets of which I have the honor to lay before you, I have tried to remedy these defects as far as possible, to remove the errors and mistakes into which writer after writer had fallen, by copying and quoting one after another, to prove all and hold fast the good.

If we look now for results, we will find that materia medica as a science has benefitted materially from these researches, that the *armamentaria* of the unprejudiced physician has been increased with advantage, helping to raise medicine in some small measure at least out of the mire of empiricism. The medicinal properties and uses of these munificent gifts of Nature have become better known among the people, and drugs that before were confined to districts, have spread to larger and more needy areas. But while the example of Government is to be taken as our criterion in many instances, it is not so in this particular case. It is surely a reproach that in the latest list of medical stores for hospitals in Bengal only one country medicine—the herb *chiretta*—appears. This surely reflects either on the internal or external administration of the Medical Store Department.

It is in view of such considerations as these that I would endeavour to offer some practical suggestions as to how the more important of our indigenous drugs may be dealt with, not merely as indifferent substitutes for European products, but each as filling a place of its own in point of usefulness and therapeutic value. The first consideration is that of *Identification*. This will remain a prime difficulty until certain prominent characteristics of each drug become established, as no amount of verbal description will enable the non-botanical mind to identify some plants and parts which even in themselves do not invariably present quite the same characters. The ease and cheapness with which almost all the drugs of this country are to be obtained, will be facilitated greatly with the help of the vernacular names peculiar to each district, as also of the professional castes who deal in these substances, the *Musheras* of Central and Upper India, the low caste *Maulas*, *Bagdis*, *Kaibartias*, *Pods*, *Chaudalas*, *Kaoras*, and *Karangs* of Bengal and the *Chandras*, *Bhils*, and *Gamias* of Bombay. These humble communities of the several Presidencies of India can render immense service to medical men in supplying medicinal plants. This fact was fully recognised by Sir WILLIAM JONES, the President and founder of the Asiatic Society of Bengal. In the second volume of his "Botanical Observations of Select Indian Plants" he wrote:—

"I am very solicitous to give Indian plants their true Indian appellations; because I am fully persuaded, that LINNÆUS himself would have adopted them, had he known the learned and ancient language of this country. * * * Far am I from doubting the great importance of perfect botanical descriptions; for languages expire as nations decay, and the true sense of many appellatives in every dead language must be lost in a course of ages; but as long as those appellatives remain understood, a travelling physician who should wish to procure an Arabian or Indian plant, and without asking for it by its learned or vulgar name, should hunt for it in the woods by its botanical character, would resemble a geographer, who, desiring to enquire by name for a street or a town, waits with his tables and instruments for a proper occasion to determine its longitude and latitude."

The suggestion herein conveyed has been carried into effect in such names as *Athrocaphalus Cadamba* and *Cedrus deodara*, but it is to be regretted that it has not been possible to widen the system in the nomenclature of plants peculiar to India.

Botanically, many of the doubtful points relating to the plants yielding these drugs have been set at rest for ever in Sir JOSEPH HOOKER's colossal work on the Flora of British India, now completed in all but the grasses, while the indexed collections of authentic specimens which are in process of formation at the Imperial Museum, Calcutta, and the Imperial Institute, London, to which the Dictionary of Economic Products is to form the catalogue and key, will, when complete, facilitate the identification of these products for commercial purposes. All the well-oiled machinery of this official mill, however, will not familiarise our acquaintance with native medicines, so that we leave the theoretical and move into the practical. I would suggest a further step in the establishment of facilities for the supply of reliable preparations for immediate use by physicians. It is vain to expect medical officers to assume the rôle either of botanists or druggists. That is a condition of things which has long gone by. I have to suggest, therefore, that the medical storekeepers of our respective presidencies should be asked to make some definite pharmaceutical preparations at their respective laboratories for distribution to the various hospitals and dispensaries for trial and report. In this way a step would be made towards their practical utilisation, while the advisability or otherwise of their replacing costly imported drugs could be most readily determined. Absolute dependence ought not to be placed on individual opinion, for such may be formed from preconceived notions or may be affected by influences or considerations which may detract from their real value. Some such arrangement once thoroughly established, however, the great Indian Medical Service will be a source of unlimited blessing to the people and will be independent of the *in-uses* and the *out-uses* and the innumerable synthetical monstrosities of these latter days. The particular class of preparation I would favor is the general one of *fluid extracts* as originated in the United States Pharmacopœia, one part of the product representing one part of the original drug operated upon. They present the advantages of portability, permanence and adaptability, with concentration and uniformity. I have myself made several experiments in this direction, the results of which I have the honor to present for your inspection. I am persuaded

that the future of Indian Pharmacology depends largely on considerations such as I have indicated to you.

The next important point is the commercial aspect of this question. The Government of India has encouraged with a liberality beyond all precedence, the cultivation of medicinal plants suited to India, and the experimental cultivation of others which have proved to be unsuitable to the soil. The result has been, on the one hand, that the cinchona industry of the world has been completely revolutionised, ruined, some will say, while on the other, thousands of rupees have been spent to practically no purpose in the attempt to establish ipocacuanha. The time has now come for laying out Medicinal Plant Farms in the districts most suited to the drugs which it is proposed to grow. There is enough belladonna on the Himalayas to supply the world, which, if transplanted, and carefully cultivated, would surely at least save India the necessity, if not the cost, of importing this among many other drugs which might similarly be grown. The gardens for medicinal plants and essential oils of Germany and Belgium are sufficient evidence of the success attending such enterprise. Another most desirable step which would follow this in natural sequence, would be the establishment of a drug emporium for India. This for obvious reasons would be most practically effected at Calcutta. A class of drug brokers would arise, whose business it would be to encourage the systematic collection of drugs for export to the great markets of Europe, Australia, and America. The sorting of the drugs into their various qualities could be effected quite as easily in Calcutta as in the London market, and the present anomalous position of the Indian druggists importing drugs which have already been shipped from India will be done away with. There are thousands of tons of valuable roots and flowers, and fruits and fibres rotting in the jungles every year for want of a proper market in which to have their approximate values appraised. Nor even on the Himalayas are they so very inaccessible. The gentian grubbers of the Alps spend weeks at a time far away from their homes collecting for the market. Some of the medicinal plant farmers about Brussels employ 500 collectors—whole families—who go out into the surrounding districts and collect the drugs which they prepare for the markets of the world. With the cost of labor at a minimum in India and material in profusion, success in some corresponding degree is assured. The ever-improving railway communication should afford a great impetus to such an industry, which I am confident would in time become one of considerable importance to the people of India.

Above all I would appeal to my countrymen to be honest. It is unfortunately too true that the art of sophistication and adulteration as applied to almost every commodity produced in India, has served to weaken the faith even of our own countrymen in what we are accustomed to call "country products." There are certain branches of industry, it must be admitted, where this process of sophistication provides quite an art of no little importance, but I ask is this sufficient compensation for a diminished faith and consequent depreciation in value, in our exports to European markets? I do not say that we are even approaching in ingenuity

to that country which created the "woolen suitings," but I hold that the success of all that I anticipate for the indigenous drugs of India depends upon this consideration. If I may present one or two instances in the brief space now at my disposal, I would remind you that *Cannabis indica* has lost a very considerable portion of the reputation it once had in European practice on account of the fact that it is not of the same standard of quality that it was in former years. Similarly, the bark of *Holarrhena antidysenterica*, the *kurchi*, is losing its undoubted position as a specific in dysentery through the substitution of worthless barks. The aconites are equally unreliable.

Among the most important of the drugs exported at present are: *Aconitum ferox*, nux vomica, Indian opium, bael, hemidesmus and Indian hemp, while among others which might form equally important articles of export are belladonna, taraxacum, podophyllin, jalap (*Ipomoea turpethum*), *Holarrhena antidysenterica*, gurgjun, chaulmurga, isaphgul.

I am hopeful that considerable encouragement will be afforded to the better appreciation of our indigenous drugs by the fact that some are likely to be included in the proposed Imperial Pharmacopœia.

In a paper which I prepared for the International Pharmaceutical Congress held in London in 1881, and which was presented on my behalf, I suggested several drugs as worthy of inclusion in a proposed revision of the *British Pharmacopœia*. These suggestions are embodied in the following list:—

| SCIENTIFIC NAME. | POPULAR NAME. | PROPERTIES. |
|--------------------------------------|-------------------------|----------------------------------|
| <i>Adhatoda Vesica</i> .. | .. <i>Bakas</i> .. | An Expectorant. |
| <i>Andropogon Paniculata</i> .. | .. <i>Creat</i> .. | Feverifuge. |
| <i>Azadirachta Indica</i> .. | .. <i>Nim</i> .. | Bitter Tonic and Anti-periodic. |
| <i>Calotropis Gigantea</i> .. | .. <i>Madar</i> .. | In <i>Rozema</i> . |
| <i>Carica Papaya</i> .. | .. <i>Papaya</i> .. | Source of <i>Papain</i> . |
| <i>Dipterocarpus Turbinatus</i> .. | .. <i>Gurgjun</i> .. | Substitute for <i>Copallin</i> . |
| <i>Garcinia Mangostana</i> .. | .. <i>Mangosteen</i> .. | Astringent. |
| <i>Gynostemma Odorata</i> .. | .. <i>Chaulmurga</i> .. | In <i>Leprosy</i> . |
| <i>Holarrhena Antidysenterica</i> .. | .. <i>Kurchi</i> .. | Specific in Dysentery. |
| <i>Psoralea Corylifolia</i> .. | .. <i>Dabchee</i> .. | In <i>Leucoderma</i> . |
| <i>Symplocos Baccifera</i> .. | .. <i>Lodhra</i> .. | In <i>Menorrhagia</i> . |

I have now attempted in the brief space at my disposal to place before you some of my views and some of my expectations which, in my old age, I cannot hope to see realised, but which, in the best interests of the great Oriental Empire of Her Majesty Queen Victoria, I venture to hope may be furthered in some measure by this Indian Medical Congress.

SHEEP'S THYROID IN GRAVES' DISEASE.

DREYFUS-BRISAL claims that thyroid treatment is not equally suited to every one suffering from Graves' disease, as it often aggravated the symptoms, and BECLERE reported a like experience, but J. VOISIN obtained excellent results in a female aged 32, suffering from Graves' disease, and to whom he prescribed 6 to 8 grammes (i.e., 93 to 124 grains) of sheep's thyroid daily, suspending treatment for ten days in every three weeks. Improvement began after a fortnight of this treatment, the heart beats becoming equal: fell from 150 to 100 per minute, the edema of the lower limbs disappeared, and the exophthalmos and enlargement of the thyroid appreciably diminished. There has been no relapse and the improvement progressed so much that, beyond a trifling swelling of the neck and very slight exophthalmos, no other symptoms of the disease can be observed.

HILL DIARRHOEA, ITS ETIOLOGY, PATHOLOGY, SYMPTOMS AND TREATMENT.

By Surgeon-Major A. ADAMS, M.D., I.M.S.

Chief Medical Officer, Rajpootana.

Definition.—An obstinate form of diarrhoea characterised by copious pale, liquid, frothy motions, is met with at all hill stations in India, and is known as hill diarrhoea.

Etiology and Pathology.—Exposure to damp night air or any chill-producing condition, in high altitudes in warm countries, gives rise to this form of diarrhoea, in constitutions relaxed by weak digestion, malaria, long residence in the heated plains, or by anything which depresses the vasomotor centres and lowers vitality. The rarer and cooler atmosphere of great elevations, acting on the relaxed skin and cutaneous nerves of such individuals, suppresses perspiration and drives the blood to the viscera. The clogged digestive glands pour out deteriorated secretions which fail to produce the proper materials of alimentation, and the intestinal canal takes on a vicarious action to remove the fluids which should have been excreted by the skin. Under these morbid conditions of the alimentary system, the saprophagenous bacilli and fungi indigenous to that region, take on unusual activity, multiply inordinately and form poisonous ptomaines which irritate the mucous membrane of the intestines, hinder absorption, and have to be thrown off with the semi-digested food and other excreta.

Malaria and defective pancreatic secretion have been assigned as the causes of this malady. Hill diarrhoea is however more common during the damp weather of the early monsoon than in the fever season, which follows the rains, and there is no indication that the pancreas is more affected than the rest of the chylipoietic organs.

Symptoms.—This disease is more common among new arrivals than among the old residents of hill stations. It generally begins with two or three light coloured, copious, liquid frothy motions, daily, or it may be ushered in by bilious vomiting and purging, after which the motions take on the above characteristics. On assuming the erect position in the early morning or on taking food or drink, one of these motions is voided, this is accompanied by a sense of relief, and is without pain or straining. The patient feels languid and distended, and although the appetite is generally fair, there is a want of satisfaction when food has been taken, much flatulence and diminished confidence in the sphincters are experienced, which make solitude desirable. The skin is shallow and shrunken the tongue furred and generally yellow, the pulse soft and weak, the liver slightly congested and sometimes tender on pressure. The extremities are usually cold, and emaciation sets in early on account of the rapidity with which the fluids are removed from the tissues. When the disease is protracted the motions become more frequent and watery, fever, dysentery, or oedema may supervene, or the sufferer may sink from exhaustion consequent on malnutrition.

Treatment.—The indications for treatment are, to restore the action of the skin and liver, disinfect the bowel and destroy the active bacilli, stop the alvine excretions and aid the digestive secretions. Time should not be lost, as this disease is much more tractable in the early stage.

The patient should be confined to the house, and bed if the symptoms be severe. The body and extremities should be kept warm, a peptonised milk diet should be adhered to if milk can be taken, otherwise broths, soups, light puddings and toast, and papain or symine should be given regularly. A glass or two of sound port should be allowed to those accustomed to stimulants, but large drinks of hot or very cold fluids should be interdicted, also meat and solids generally.

The salts of mercury are among the most patent drugs in the treatment of this disease, and the perchloride is the most efficacious of this group. Salol and Resorcin have both been found to act well in this affection, and I now generally treat cases with 15 or 20 grains of salol three or four times a day, and a bismuth and Dover's powder at bed-time, with excellent results.

The salol destroys the bacilli and disinfects the bowel, the dose of Dover's powder and bismuth at bed-time gives a good night, reduces the peristaltic action of the intestines, soothes and astringes the irritated and congested mucous membrane, and stimulates the action of the liver and skin.

Quinine, nux vomica, and hydrochloric acid make the best tonic in this complaint, and a *sherbut* from fresh bacl fruit is very useful in the chronic stage of the disease. A sea voyage or change to the sea-side will often be found beneficial in protracted recovery.

—:—:—

RADICAL CURE OF CHRONIC DYSENTERY IN ITS RECURRENT FORM, BY WASHINGS OF THE LARGE INTESTINE WITH A SOLUTION OF NITRATE SILVER AT 1-1000.

BY HENRY GALLAY, M.D.

Surgeon Major for the French Colonies.

I have the honor to lay before you a series of cases which I think and trust will be found to be of the highest interest to all medical officers and practitioners in India:—

The succinct clinical statement of these cases, in fact, shews that it is possible, without much difficulty, by setting aside all the therapeutic substances which are to be absorbed by the stomach, and notwithstanding, allowing the sick persons, to feed themselves as they like, it is possible, I say, to cure old chronic dysentery especially when this disease is assuming the form which is called the *repeating form*. And this result can be obtained simply by performing a daily and continuous series of washings of the large intestine with a solution of which the following is the formula:—

| | | |
|-------------------|-----|------------|
| Nitrate of silver | ... | 1 scruple. |
| Distilled water | ... | 1 litre. |

Case I.—Dr. G., a medical officer, while residing in Tonkin, in 1883, contracted acute dysentery. During four years he had 14 relapses of the same disease, in spite of all known and suitable treatment, in spite of ten months' strict diet, between the sixth and the seventh relapse.

* Being a paper read at the Indian Medical Congress and sent to the Record for publication.

It was after the eleventh relapse that Dr. G., following Dr. LE DANTEC's advice, felt inclined to try on his old and tenacious disorder, the washing of the large intestine with the above solution, which washings had already been successfully tried by his eminent friend and colleague against acute dysentery.

Four several times (a series of ten washings each) shewed at each time a period of apparent recovery lasting from forty to fifty days. But with such an amelioration in the general state of health, such a feeling of relief from pains, that the intervals which formerly separated the attacks, and which the patient used to call his periods of quiet, now seemed to him dreadfully unbearable. So after the fourteenth relapse, Dr. G. decided to begin an indefinite series of washings.

This series of washings lasted thirty days, and were then interrupted, Dr. G., having had to leave France. But since leaving Marseilles, the recovery, which he supposed not to be a complete and definite one, has not however, until now, failed (August 1892). Besides, from that day all precautions as to diet have been put aside, recovery being more and more confirmed (7th September 1894).

Case II.—Mr. X., Revenue Officer at Saigon, was suffering for two years from dysentery in a recurrent form. He had tried every sort of treatment. Even in moments of quiet, he suffers and passes mucus through the anus.

At Bordeaux, in June 1892, he underwent a series of twenty washings, and then wrote to me saying that he has never been so well.

In reply, I advised him to repeat the series. Since I have left France I have never heard of him; but what I have learnt from experience, permits me to conclude that he did not require any more aid from me.

Case III.—Miss D., 14 years of age, an Indo-European, had dysentery in April 1892, and was cured in 15 days. But suffers since from constant uncontrolled stools in the morning. Frequent indigestion which gives rise to ejection of mucus and bloody matter, with tenesmus of the anus, sleeplessness, and pains when the flatus passes in the colon.

September 1892.—Series of 20 washings. Complete amelioration. The series was kept up as a precaution, to 50 washings.

September 1894.—The cure has been confirmed up to this time.

Case IV.—Mr. D., Colonial Functionary, had contracted dysentery at Hue in May 1889. Notwithstanding twice returning to France and the use of the waters of Bussang, he was always suffering and was subject every now and again to relapses. He lost 24 lbs. in weight. In January 1893 he began a series of 80 washings with, complete amelioration. In July 1894, two years later, Mr. D. left Pondicherry having regained his weight.

Case V.—Miss X., 18 years, European, had dysentery in 1891 at Hyderabad. Since she has never passed two months without a relapse. In May 1891 she had a series of washings up to 50 only with perfect amelioration. I heard of her a year later, and the cure was maintained.

Case VI.—Rev. Father P., missionary in Tanjore, contracted dysentery in 1890. Since he has had alternately and constantly, constipation and mucous diarrhoea with tenesmus. Series of 80 washings. Complete cure. He has been able to resume his hard work, while he had scarcely any strength at that time, in 1892; and to-day, September 1894, he came to shew himself to me: he is stout, fresh and vigorous.

Case VII.—Mr. P., Controller of Revenue accounts at Pondicherry. Acute dysentery in 1888. Since constant relapses. In July and August 1893, series of only 56 washings. Complete amelioration, which is confirmed now in September 1894.

Case VIII.—Mrs. E., 21 years, European, has had dysentery in a repeating form since the age of 15 years. Greatly weakened. Chlorotic and always suffering. In October 1893, she began a series of 50 washings. Complete cure with ten washings. In June 1894 she went away to Europe, strong and fattened, with an additional weight of 4 pounds and bearing without difficulty the commencement of pregnancy.

I have, of my own account, shortened the clinical description of the above cases, the details being the same for each of them.

Considered, on the whole, they shew the reader that:

By means of sixty washings with ultrate of silver solution, I have succeeded in curing myself from a repeating dysentery which persisted for four years, and that, emboldened by this personal example, I have also succeeded in curing seven other patients from dysentery from one to five years' standing.

I must now indicate the way of proceeding methodically with the antiseptic washings of the large intestine. This method is very important, and the final success or failure depends exclusively on its proper and rational application.

The process I make use of is the same as that indicated some time ago (September 1890), by Dr. LE DANTEC (in *Archives de Médecine Navale*), against acute dysentery.

The patient should lie down on his right side, his left thigh being bent, in short, he will occupy the same position as if a digital exploration of the rectum were to take place.

Keeping this position, first an enema of tepid water destined to empty out, wash and clean as completely as possible the large intestine, will be given.

After evacuating this first washing given for cleanliness, the patient will assume again the same position as before, and then the antiseptic washing will be applied:

| | | |
|--------------------------------|-----|-----------------|
| Nitrate of silver crystallised | ... | 1 scruple. |
| Distilled water | ... | 1 litre. |
| Laudanum | ... | 20 to 30 drops. |

and will try to keep it in for a few minutes. Two, three or five minutes are the maximum.

It is proved by numerous experiments made on dead bodies that to fully ensure the washings of the colon up to the coccum, one litre at least of liquid is indispensable, when the experiment is made on adult corpses, but on the corpses of children, four or five hundred grammes are enough.

In order that the solution may be kept in by the large intestine for some minutes, it is necessary to make use of a rather long clyster-pipe and to get it pretty deeply thrust in so as to pour the liquid into the very cavity of the rectum, and thus not rouse too quickly the sensibility of the anal sphincter.

The pressure of an "Eguis's syringe" is sufficient to push on the liquid up to the cœcum, provided that it is quickly done, for the instrument being made of metal may cause a change in the nitrate salt if delay occurs.

An ordinary India-rubber enema syringe may also be employed, but sometimes its jerky ejaculation provokes inconvenient muscular contraction of the large intestine which often prevents the retention of liquids.

The best apparatus is an ordinary glass funnel, the slender portion of which is adapted to a rubber-pipe about two and a half yards long. A forceps squeezing the pipe allows the funnel to be filled. An assistant then lifts the funnel up in order to give the liquid a sufficient pressure, while the patient himself holds the clyster-pipe in a suitable position.

An enamelled iron receptacle fixed to the wall or to a partition is even better than the above described apparatus, for the patient is able to operate on himself without any assistance.

The silver nitrate solution, after staying for a few minutes in the colon, will be evacuated sometimes in one effort, sometimes in two, the second evacuation being separated from the first by a few hours' interval.

The only ordinary immediate consequence of the washing is a sensation of stricture at the lower part of the rectum. But this sensation, after a quarter of an hour at most, passes away.

Sometimes, but rarely, except in some very impressionable patients, the washing is followed by cramps of the stomach.

These cramps seem to be nothing but muscular contractions in the coats of the transverse colon. They are besides of short duration and are mastered by simply staying in bed.

This is the reason why I always advise patients to apply their washings in the morning, as soon as they awake. So, if they feel any cramps, they can find again at once the useful and pleasant warmth of the bed they have just left, and after an hour's rest they will do well for the rest of the day.

Out of seventy washings which I underwent, I have only three times felt the above-mentioned cramps. At any rate, this slight inconvenience did not prevent a young boy of fourteen, and a young girl of eighteen years, from bearing the treatment up to the end (Cases III and V).

Often, from the first washing, the amelioration is complete. One can, at any rate, rely on the third or fourth washing.

The patient suffers no more, sleeps well, and goes to the stool once or twice a day. The painful flatulence and twisting gripes ceasing are signs of recovery.

These signs are more perfect, when, at the fifth or the tenth washing, I allow the patients to lay aside all precautions regarding diet, and he who, for several months,

has suffered from hunger will certainly understand that I consider this point as one of the greatest advantages of the treatment I am now recommending. The patient is already stronger and more alert, and is henceforth living like any one else. He must not however be left to himself. Four times I have myself noticed the insufficiency of a too short series of washings. However great may be the antiseptic power of nitrate of silver, it does not cure in a few days an affection so inveterate as chronic dysentery.

Whether it is because the microbian agglomerations infiltrate the deep coats of the intestine, and are thus sheltered from the first attacks of the antiseptic salt, or because the antiseptic itself, coagulating the albuminoid substances on the surface of the ulcerations, shelters the deeply hidden microbes, or on account of the persistence of the spores, or simply because the ulcerations, even when freed from the microbes which keep them in bad order, cannot be cicatrised in three days and thus remain quite ready for a new sowing from the ordinary inhabitants of the large intestine, be that as it may, recurrent dysentery requires continuous attention. The treatment must be pursued for a sufficiently long time, so that the newest spores may have enough time for hatching, or the last ulceration, time for becoming cicatrised.

I have, by a groping process, been enabled to verify on my own intestine how very insufficient are too shortened series of washings.

Since then, therefore, I have always recommended to continue till the sixtieth washing, and it has, on every occasion, been enough.

Two of my patients, owing to removal, have been obliged to cease at the fiftieth washing, however in fifteen and eighteen months they have not had a relapse.

But in this case, it is always better to apply more than enough, and when definite recovery is the certain result, what trouble is it for an already cured patient, who has recovered his appetite, plumpness and strength, to persevere for a few days more in the precautions which he is already accustomed to?

Sixty washings have always been enough even for dysentery of four or five years' standing. I do not, however, reject the possibility of seeing the disease return, even after this period had expired, and in such a condition, I would see no inconvenience in doubling the duration of the treatment. I am, moreover, sure that the patient will raise no objection to my prescription.

The first trial, even when not attended with success, will have given him faith in the washings, his general state of health will have been so much altered for the better, his well-being so far different from his best moments of the time past, that he will be the first to have recourse to the treatment which has already relieved him.

I went through the same state of mind before finding this remedy, which I did not much rely on. And, I must confess, that I had arrived at the point of considering my affection as a permanent infirmity and the prospect of definitely undergoing a daily or bi-weekly washing, as a very desirable result, since, by doing so, I was able to enjoy all the advantages of health.

It is chiefly with this idea that I undertook the long series, which has been interrupted only by my departure to India.

My full recovery, since my departure from Marseilles, has been an unexpected result, and remains the inciting example I always offer to dysenterics who, more or less, are disheartened, and sceptical regarding new modes of treatment.

He who has followed my example has never been deceived. And it is guided by the hope of being profitable to a large number of suffering people that I have made this attempt to inform colonial medical men of the results I have obtained in so tenseous an affection as recurrent dysentery, by a method of treatment which in my hands has shewn itself as easily borne as it is quickly effective.

—:—

A CURIOUS CASE OF HUMAN SACRIFICE, ITS MEDICO-LEGAL BEARINGS AS TO IDENTIFICATION AND MUMMIFICATION.

By ED. LEEDEK CHALKER, M.D., C.M., L.F.P.S. GLAS.

Assistant Surgeon, Berhampore.

THE scene of this tragic spectacle of human sacrifice was a temple sacred to the goddess *Kaluva* or *Kali*, in a village 7 miles from Berhampore (the capital of the Ganjam District). The shrine is under a tamarind tree and consists of four stone figures. Five men named BALAJI MAHARANA, BALLA JENNI, alias BALAJI PATRO, BHARTHO SRTTI, TARINI and BENNU BISSOYI, of whom BALAJI MAHARANA, a carpenter by trade, was the *guru* or teacher, used to visit the temple of this goddess on Tuesdays and Saturdays for performing worship. They also practised sorcery. About a month before the day of the murder, at one of their usual meetings beneath the tamarind tree, they had arranged that a human sacrifice should be made to the goddess—this being considered necessary to improve their knowledge of the black-art. The victim was not then decided upon. Subsequently the *guru*, BALAJI MAHARANA, who was the chief of this band, resolved that TARINI, one of themselves, should be sacrificed without his knowledge, and prevailed upon the remaining three to consent to the bloody deed.

How this fatal deed was done had better be described in the words of an eye witness and participator, BALLA JENNI and the others were tried and convicted by the Sessions Judge of Ganjam, and the conviction of BALLA JENNI was confirmed by the High Court. In his examination before the Committing Magistrate he prostrated himself and made the following statement:—

A knife is about to fall on my throat. I shall tell you truly what I have seen. A carpenter, BALAJI MAHARANA, one BENNU BISSOYI, a washerman named BHORTIYA, myself and IRRILI TARINI had been contemplating for the last month about making a human sacrifice to the goddess. We five persons used to go together. BALAJI MAHARANA suggested that he would sacrifice somebody before the goddess. He then spoke to me thus:—"We cannot get other people. TARINI is a constant companion with us. We and TARINI have confidence in each other. Therefore, you had better bring him with you." We sat at the front of TARINI's house. I and TARINI sat there. We then went, taking with us a bottle of liquor, a fire brand and this bundle of peacock's feathers. On the way we saw BALLA BAYARI and DUALABRO MOLIKO.

They went away in that direction. We sat near the goddess for a *ghari* (a little while). After we sat there for a *ghari*, these three people came. The carpenter worshipped the goddess and made the following offerings, viz., a cake made of parched rice and jaggery, flowers of the mandara tree, a new earthen pot, and a casket. After that the carpenter prostrated himself before the goddess, after that BENNU BISSOYI prostrated himself, after that the washerman BHORTIYA prostrated himself, after that I prostrated myself and after that TARINI prostrated himself. We then drank the liquor that we had taken in the bottle. We again prostrated ourselves before the goddess. TARINI drank the greater part of the liquor. Our *guru* (teacher) is the carpenter. Much liquor was given to him. TARINI prostrated himself. He could not get up for want of his senses. The washerman had a knife in his hand. He gave him a cut. BENNU BISSOYI was standing by and caught hold of the hair. The carpenter was standing in the other direction. He caught hold of the legs. The head was not completely severed from the trunk, but was only slightly attached to it. The washerman made another cut to remove the head completely. After that the carpenter cut the lower lip. He also cut the tongue with a small knife. After cutting, he sprinkled a little blood on the mandara flowers and again worshipped the goddess. He then recited prayers bit by bit. After prayers he made worship again and then presented perfumes. He then offered raw rice and fresh grass. He placed the tongue, the nails and the hair of the deceased near the new earthen pot. He then tied them all into a bundle. BENNU BISSOYI and the washerman pulled away the trunk. He (carpenter) took the head to the original goddess *Kaluva* by the western direction. He is our *guru*, and he called us. We accompanied him with a fire brand from outside the village. He had in his hands 7 mandara flowers. He cut up 7 pieces of flesh and performed worship. We then came away, taking the head with us. There were ear-rings on the head, both *woli* (lower ear-rings) and *guna* (upper ear-rings). BALAJI MAHARANA took up my *gamanchu* cloth and tied them up. He told me to preserve it for four or five days. After that I brought it and kept it with me in the *odagoni* (store-room). He wrapped the head with something and threw it in the tank, called Benabondho, on Sunday night. I was made to take an oath before the goddess by the carpenter, and I was made to promise not to reveal the matter. The carpenter said: "TARINI is your constant companion. It will be suspected that you only killed TARINI. You will be caught hold of. Even if your throat is to be cut, you should not admit guilt." I did not go to touch the dead body, because I was afraid. I said to him: "He is our sincere friend. How can we kill him?" Thereupon the carpenter, who is our *guru*, rebuked me saying ".....! Why do you say anything about it? I then became afraid and kept quiet. I went away to some distance out of fear and sat there.

Q.—You mentioned five names—carpenter BALAJI MAHARANA, BENNU BISSOYI, BHORTIYA SRTTI, and yourself and TARINI. What were you five people at the habit of doing?

A.—On Saturdays and Tuesdays we used to go together to the goddess.

Q.—Did BALAJI MAHARAYA suggest sacrifice to all of you or to you alone?

A.—He made the suggestion when we were all sitting together. The suggestion was to sacrifice somebody.

Q.—When did he make the suggestion?

A.—A month ago, he made the suggestion. He said that our learning would increase if we made the sacrifice.

Q.—Did all five people consent to it?

A.—I did not consent. TARINI also did not consent; we both did not consent. The other three consented to make sacrifice.

Q.—Whom did you think of sacrificing?

A.—That matter was not decided. All kept quiet and went away. On Saturday the carpenter said to me: "You and TARINI both go in advance." He said that TARINI was to be sacrificed.

Q.—When did the carpenter tell you?

A.—He told me this on Saturday in the hottest part of the day.

Q.—What did you say to it?

A.—I said, "He is my friend. I am not at all willing. He is my confidential friend. He is a very thick friend of mine. I cannot consent to it." The carpenter then said "all right, you do not consent." He then said that we should go in advance and that the others would follow. We went in advance and they then came afterwards.

Q.—When you and TARINI went together, were you aware that TARINI would be sacrificed that night?

A.—I was aware.

Q.—You were not willing about it. How did you take him there?

A.—The carpenter is my guru. He rebuked me. He threatened me. He abused me. I therefore took TARINI with me.

Q.—When they came there, what had they with them?

A.—The washerman brought a knife. The carpenter had a vessel with water. He had also brought a new earthen pot, some mandara flowers, and a casket.

Q.—What became of the knife with which you were in the habit of sacrificing animals?

A.—I was in the habit of using a small knife, but never a big knife.

Q.—What did you do after the sacrifice was over?

A.—We all bathed in the tank of the Battini people and washed our clothes. Each went to his house.

Q.—What did you do with the head in the day time on Sunday?

A.—The carpenter kept it in his backyard, concealing it under an earthen pot.

Q.—Who threw it in the tank on Sunday?

A.—He himself threw it there.

Such is the account of the sacrifice, as given by one of the participants. The day after the sacrifice there was an uproar in the village on account of the missing man TARINI, and 30 yards away from the temple the police found a headless corpse identified by his brother as that of the deceased, by the tattoo marks on the forearm. His cloth likewise was found near the temple. On a further search being made, the head, without the lower jaw, was found in a tank close by which was almost dry at the time.

The headless body and a skull, a bundle of human hair and some horny matter along with the cloth were sent to the District Surgeon at Bahampore for post-mortem examination.

The post-mortem appearances bearing on this case were the following:—

The trunk throughout presented a black, shrivelled, leathery aspect, like a mummified body. It was intact, except at the following positions, where the soft tissues were cut into most probably with a sharp edged instrument. The edges of the wounds were somewhat regular in outline. The wounds were found in the following places:—

(a). The neck, where the head was decapitated from the trunk; the four upper cervical vertebrae were found missing, and assumed to have been attached to the head.

(b). Right side of the chest exposing three or four ribs which were not fractured or damaged in any way.

(c). Both popliteal spaces, wounds being in size 6 by 3 inches, all structures cut through, exposing the joint.

(d). A large wound in the entire perineum, exposing the anterior surface of the sacrum. The genitals were not touched.

(e). Minor injuries to the palm of left hand. The characters of all these wounds were more or less regular in outline. The edges dry, shrivelled and black. The soft tissues of the chest and abdomen were perfectly intact. All the internal organs of the body were completely removed thoroughly and skilfully. Rigor mortis was decidedly present in the upper and lower extremities.

There was no fracture anywhere. The hair of the head sent for examination was a cubit long, black, in locks and curls and matted together with clotted blood. The blood-stained cloth and the matted locks also were satisfactorily identified by the brother of the deceased. The head produced was nothing else but a skull presenting the appearance of having been buried for about six months. It was white and glistening. There was not a vestige of soft tissue on any part of it, no trace whatever of brain substance or membranes. The tongue, eyes and gums were entirely absent, and the cervical vertebrae were wanting. Such were the appearances noted on the post-mortem examination. Considering the peculiar condition of the body simulating mummification and the entire absence of the internal organs, no opinion could be given as to the cause of death.

Now I shall consider the points of interest and importance in this case.

The Identification of the Body.

(I). The body was identified by the brother of TARINI the deceased, by some tattoo marks on the fore-arm. The hair of TARINI was similar to the bits found in the pool of blood in front of the goddess Kalava, the cut portions having been carried along with the knife and lodged in the cuts made in the ground.

(II). In the second place it was very fortunate that rigor mortis was still present, as otherwise it would have been impossible to tell how long previously death had taken place. The presence of rigor mortis helped to fix the time when death probably had occurred.

The mummified appearances of the body.

The desiccated condition and black color of the corpse, which retained its natural form and was in every way preserved from further decomposition, would have given one the idea on mere superficial examination, that death had occurred some months back, and had it not been

for the rigor mortis present at the time, there would have been considerable doubt as to the period the deceased was dead.

The Egyptians, who made a special study of embalming their dead, took about 70 days for that process. The procedure they adopted was this. The corpse was kept at home till decomposition commenced. Then a deep incision was made on the left side beneath the ribs with a rude knife or Ethiopian sword. The entrails and the lungs were extracted, and the brain was removed from its cavity by a crooked instrument passed through the nose. All this having been effected, the body was ready for the salts and spices necessary for its preservation. The ingredients for this purpose, consisting of peculiar drugs, were passed through the nose into the cavity of the skull, and the belly was rinsed with palm wine and filled with resins, cassia and other substances. The incision was then stitched up. The mummy was then steeped in natron and wrapped up in linen cemented with gum. By this process the body assumed a desiccated and rusty brown color and it was then considered preserved from further changes of decomposition.

But in the case of the corpse under notice, what is it that produced almost the same appearances in such a short time as nearly 48 hours. What gave the preservative character to the body? Possibly, the chief causes at work were these :—

(1). The body being drained of the greater portion of the fluid through the large arteries and veins of the neck and popliteal spaces.

(2). The removal of all the internal organs, and

(3). The alternate cold by night and heat by day acting on the body causing a drying of the tissues and prevention of soft decomposition, which would have been the result had the body not been deprived of its blood. The disembowelment must have been made through the rent in the perineum and through the neck; and indeed it had been so nicely effected as to lead one to surmise that it must have been the work of a man accustomed to similar business. It was afterwards ascertained that one of the murderers was a butcher by calling.

It is more difficult to account for the appearance of the skull produced, if really it was that of the man killed two days previously. It is easier to believe that it was exhumed from some grave and brought on the stage simply because a skull was thought necessary to complete the case.

Apart from the above considerations, this case also suggests the idea that there is some connection in the Hindu mind between sorcery and Kali worship. As the District Judge said in his judgment, "the reference to the removal of the thumb, the tongue, the hair and nails from the person, will suggest to any one acquainted with the subject, a strong confirmation of the fact that the murder was indeed a human sacrifice of a kind, at one time no doubt not uncommon, but which is regarded now as a curious relic of antiquity."

Miss Freany K. B. Cama, M.D., has been appointed House Surgeon, Pestonjee Homajee Cama Hospital for Women and Children, Bombay.

Surgeon-Major E. Ferrand, I. M. S., has passed the examination for the coveted diploma of F.R.C.S., Eng.

A MIRROR OF PRACTICE.

PINEAPPLE AND PAPAYA FRUIT AS ANTI-TOXINS AND SOLVENTS IN DIPHTHERIA AND DIPHTHERITIC SORE-THROAT; ILLUSTRATED BY FOUR CASES.

By E. W. CHAMBERS, L.M.S. Cal., L.S.A. Lond.
Coroner of Calcutta.

Case I.—A lady of a religious sisterhood, in a large educational institution under my medical care, was suddenly taken ill with fever and a bad sore-throat. In 24 hours diphtheria of a severe type showed itself. The tonsils, fauces and throat were covered with the characteristic false membrane, and the symptoms generally pointed to a rapid fatal termination. Tracheotomy was contemplated but abandoned, as the case seemed hopeless. I resolved to try the effect of papaya fruit. A half ripe papaya was got and cut into small pieces. The patient was directed to eat a piece every hour, and some of the expressed juice of the fruit was applied to the fauces, tonsils and throat with a cotton swab, every three hours.

In a few hours the urgent dyspnoea and acute febrile symptoms subsided. Next day the membranous deposit was distinctly less, and within another 24 hours the membrane had disappeared and the throat was clean, though raw and inflamed-looking still. The subsequent convalescence was uncomplicated.

Case II.—A native attendant of Case I got diphtheria in a bad form, and was treated exactly as her mistress was, and made as easy and good a recovery from the use of papaya.

Case III.—Another religious sister became ill and was very bad with diphtheria. In her case, in addition to the papaya applied to the throat and eaten, I prescribed pineapple in small pieces every hour, alternately with papaya. This combination seemed more favorable by its more rapid and salutary action than papaya alone. A cure was effected in four days, while relief and evidence of recovery began within a few hours of commencing the treatment.

Case IV.—A Eurasian lad, suffering with diphtheria in a severe form, was given pineapple only. The membranous deposits disappeared in two days, but a quinsy remained, and as he was unable to get proper nursing at home, he was removed to the Presidency General Hospital and recovered in a few days without any return of the diphtheritic deposit.

Remarks.—The following is the method I advise for the use of papaya and pineapple in cases of diphtheria. Get a few raw or green papayas; express the juice and with it freely cauterise the fauces and throat every hour or half-hour, or oftener, as the symptoms may demand. Also peel and slice the papaya salt it and let the patient keep chewing this and swallowing the juice, but carefully throwing out the chewed pap. Also get a pineapple; crush out the juice, and let the patient sip this all day, or else cut it into slices and let him masticate it and swallow the juice. In a few hours the diphtheritic growth will be destroyed; but the chewing of the papaya should be continued for a day or two, and the pineapple should also be taken for five or

six days. *Diet*: Nourishing soups, with light wines. The patient ought to drink nothing hot or warm, and be kept in a comfortable room with good ventilation, away from draughts.

The use of these fruits in this dread malady is nothing new, nor ought I to be credited with the discovery of their great therapeutic value in diphtheria. Some years ago, a friend who had lived for many years in Natal, told me that the Kaffirs or natives of Southern Africa, use the pineapple freely and generally for the cure of diphtheria, and their success has robbed this scourge of its terrors, for very few of them who use this remedy ever die from the disease. I have used papaya for diphtheria and diphtheritic sorethroat for some years with invariable success. So far as papaya goes, its solvent properties are well known. It causes rapid disintegration of meat and other nitrogenous substances with which it is brought into contact. Its value as a solvent of fleshy growths, malignant or benign, was first mentioned to me by a *hakim*, and I have used it with some measure of success in lupus, epithelioma, warts and in diphtheritic deposits.

The brief notes now given are of recent cases, and I am led to report them as I think the more extended trial of papaya and pineapple would lead to the most remarkable recoveries from diphtheria. My impression with regard to the chemical and physiological action of the active principles found in these fruits, is that they are possessed of potent germinicidal (antitoxin) and solvent properties, and I feel confident that the general use of this method will result in minimising much suffering and in saving many lives.

—:O:—

A CASE OF INFLAMMATION OF THE CEREBRAL MENINGES ENDING IN RECOVERY.

By SURGN.-CAPT. GEO. S. THOMSON, M.B., C.M., I. M. S.
Decca.

THE patient was a Marathi sepoy, aged 34, with 14 years and three months' service. Admitted into hospital, 18th March 1894 for ague, with a temperature of 101°F. morning and 103.8°F. evening, also cough and expectoration of frothy mucous. He is very restless, skin hot and dry, much thirst and dryness of the throat complained of.

Urine high-colored, tongue furred, pulse weak, 120, no physical signs of pneumonia. He had not had any previous illness. Ordered antifebrin and antipyrin if temperature be 102°F. or over, and mist diaphoretic with grs. 5 of quinine thrice: half ounce of rum with egg and milk every fourth hour. Report next morning:—Slept very little last night; much cough and some expectoration. Bronchitis present, both sides, large tubes affected, restless and disturbed; weak and prostrate, temperature 101.2°F. evening 104.8°F. tongue dry, pulse 120.

Antifebrin and antipyrin given (ana grs. 5) Slept badly, and at times was very restless and violently delirious, shouting out in a piercing shriek which could be heard at intervals a long distance. This cry was repeated about every 4 minutes, and the hands raised to the forehead at the same time. The shriek was

most distinctive and unmistakable in character, a real cephalic cry. Bowels moved once in 24 hours.

Next morning temperature 98.6°F. Pulse 76. Respiration 20. Prostrate and weak. After 10 A.M. he ceased to speak intelligently, wandered in his talk, rambling and muttering delirium. Temperature 99°F. Pulse 80. Passed water voluntarily, but motions involuntarily in the bed. Picking at the bed-clothes, shouting and talking incoherently; kept in bed by two attendants with difficulty. Blisters applied to back of neck and repeated in the evening. Calomel grs 6, croton oil 2 minims. at once Ice to suck and cold evaporating lotion to head. Twelve hours later very noisy and delirious: picking at bed-clothes, sinking down in the bed, and tossing arms about aimlessly. Applied wet pack, cold to head and nape of neck. Bromide of potassium and ammonium at once, and iodide of potassium in the evening. Ungt. hydrargyri rubbed freely into both sides of neck, and repeated in 12 hours. The rubbing in of this ointment to the soft parts lasted half an hour each time.

Next morning temperature normal; still delirious, and, tossing about, much firm contraction of the extensor muscles of the left forearm, and tremor in the muscles of the right leg, grinding of teeth, paralysis of the left side of face, and twitching of the muscles generally is distinctly noticeable. The abdomen is rather distended, and *notache cerebral* found developed on repeated trials. Pupils much contracted, insensitive to light, and skin dry. Some cough and frothy expectoration. Respiration noisy, the nostrils dilate forcibly during expiration. Bowels moved and urine passed naturally and voluntarily, evening temperature normal, pulse 86, respiration 24.

Conscious next morning, sat up and took some food during the day. Talks rationally, but complains of the blisters on the neck, which prevent him from moving his head about. Kept all day in a dark room in a separate ward and remained quite rational. On the eighth morning of the disease, and the fourth day since the cerebral symptoms developed, the report reads:—Slept well, bowels moved naturally; he went to the latrine himself without assistance. Took food with his own hands and is quite rational. No pain in head. Pupils normal. Temperature normal. Pulse 80. Respiration 20. Convalescent. No paralysis. Moved into general ward with one attendant to look after him.

On the twelfth day after his admission he was discharged as he was quite well enough to go on furlough. He has since returned and is doing all his duties as a sepoy, and to day he walked 12 miles by route march with his regiment, having perfectly recovered from his serious illness.

Syphilis and Aphasia.

DR. JOLLY reported at the Congress of German Physicians, Vienna, a case of cerebral syphilis in which he was able to demonstrate by autopsy the dependency of word deafness and aphasia on a complete destruction of the entire parietal lobe, the two first temporal lobes, the angular gyrus, pre-cuneus and cuneus. The patient was unable to read his own name, to write from dictation. The deafness JOLLY considers was due to the lesion in the temporal lobe, and the loss of speech possible to the entire destruction of the auditory centre and areas.

**VENTRAL HERNIA, RUPTURE BY VIOLENT
COUGHING, PROTRACTED PROTRUSION
AND STRANGULATION OF GUT:
OPERATION: RECOVERY.**

By JAMES R. WALLACE, M.D.

Calcutta.

THE following notes of a case of Ventral Hernia, in which spontaneous rupture of the abdominal wall with protrusion of bowel for two days had taken place, will, I hope, prove interesting. It occurred while I was Resident Surgeon to the Calcutta Medical College Hospital. Reduction of the gut was effected and a radical operation performed under antiseptic precautions.

The case which I exhibited to the Calcutta Medical Society was peculiarly interesting and so rare, that I need not apologise for going into a few details of its history and treatment. Our subject is a middle-aged, sparely built Mahomedan male, by trade a fruiterer, and has seldom been "sick or sorry" in his life. He has enjoyed such good health indeed, that he tells me the most serious illness he has had, has been a *toothache*. About six months ago however his troubles began, and he was admitted into the Medical College Hospital with a fairly large sized abdomino-parietal abscess, extending from a point an inch below the umbilicus in the middle line, to an inch and a half from the left anterior superior iliac spine. This was opened at its most dependent point, i.e., near the iliac spine, and about ten ounces of pus let out; the abscess cavity readily contracted and the incision was healed within a fortnight, when he was discharged from hospital. There was no hernial protrusion at this time. A month later however he found a small soft, compressible swelling had formed just at the site of the incision, about the size of a walnut, and simultaneously another of equal dimensions made its appearance about an inch below the umbilicus. These tumours enlarged perceptibly, when at the end of five months the upper one which had increased in size more rapidly than the other, was about as big as a large orange. The patient states that they caused him no pain; that in the recumbent posture the swellings disappeared, leaving only the wrinkled skin to be seen outside. On the night of the 1st October (11 P.M.) he says that he had a violent fit of coughing during which he felt a sudden twinge of pain at the upper swelling and perceived at the same time a small knuckle of gut shewing itself through the tear. He was about a mile from home when this accident occurred, and he walked the whole of this distance to reach it, and then found on his arrival that a much larger portion of the intestine was extruded. He tried several times to push back the protrusion but to no effect, till, disappointed with his own efforts, he sought admission to the Medical College Hospital after travelling from his house a distance of nearly fifty miles by palanquin and partly on foot. He was admitted at 12 P.M., on the 3rd October, i.e., forty-nine hours after the rupture of the hernial sac and the extrusion of the gut. I saw him at this hour and found him much exhausted; his expression was one of extreme anxiety, his breathing shallow and hurried; the extremities cold and his skin bathed in clammy perspiration. On inspection I found a large coil of the small intestine (ileum) pushed out of the abdominal cavity uncovered by peritoneum, but coated with a thick layer of recent lymph, which adhered to the external coat of the gut and partially agglutinated the apposing adjacent surfaces of the coils. One or two ecchymosed patches and a general turgescence of the outer coat of the exposed intestine were plainly visible.

I resolved to wash the gut and to return it into the peritoneal cavity, and accordingly under thorough antiseptic precautions I bathed it with a weak solution of carbolic acid, and endeavored gently by taxis to reduce the hernia, but fruitlessly; for the gut was constricted and partially strangulated at the inner opening of the hernial

sac, and I found it necessary to pass a bistoury guarded by my left index finger into the sac to free the obstruction, and did so by making an incision upwards in the median line about a quarter of an inch. This was amply sufficient, for on a little further manipulation the gut passed inwards very easily. I now entered my finger into the sac, and even explored with it the peritoneal wall adjoining the seat of constriction to be assured there were no adhesions between the gut lower down and the parietes. I found no such complication and proceeded then to close the spontaneous opening in the abdominal wall by passing a continuous catgut suture along the edges of the tear, which was fully an inch in length. Having gone so far, I surmised how it would be best to obliterate the sac of the hernia, the skin covering which lay in loose folds and represented a cavity which was large enough to hold a big sized orange. I thought I would best attain adhesion between the walls of the sac and thereby radically prevent the recurrence of hernia, by passing a line of stitches along the neck of the sac. I did so by means of an uninterrupted catgut suture and then dressed the wound lightly with carbolised gauze, supplemented by a pad of the same material and an abdominal bandage with a large, heavy linseed poultice to cover the whole.

Subsequent progress.—The degree of exhaustion in which the patient was admitted, was more marked after the operation, and for a few hours the patient seemed partially collapsed. He rallied however under the influence of diffusible stimulants and local heat. For the first three days the patient had slight pain over the umbilical region; he had a little tympanitis on the third day after the operation, but both this and the pain subsided with the evacuation of the bowels which took place on this date quite naturally. The wound healed kindly and each day saw the sac shrivelling up more and more; only a little pus was found to ooze out from the external opening on the 4th and 5th day after the operation. A small abscess, totally unconnected with the sac, formed about 2 inches from the wound; this healed after incision. The patient progressed very steadily, he gained strength, had the regular use of his bowels, and really suffered from no active constitutional disturbance from the first day after the operation. To-day—the 9th November—on examining the parts two distinct hernial protrusions are seen, both situated as originally described, but the upper (the one operated on) is half the size of its fellow, though it was originally more than three times bigger than it. The sac of this tumour is found to have contracted very much the cicatrix at its summit, marking the seat of the spontaneous aperture, is firm and thick, the inner opening or rather the neck of the hernial sac is however as much open as before, and presents a tough fibrous circumference, which certainly does not seem to have been benefited by the operation. The temporary closure of the neck of the hernial sac must however have been beneficial, since it prevented the egress of the gut which would have been an obstacle to contraction of the sac. The patient owes much to his subsequent care and treatment under Dr. MULLEN, and I have no doubt that rigid attention to antiseptics and the soothing influence of the poultices which were continuously applied over the dressings for several days helped to ward off peritonitic complications.

He is now fit to return to his home, but will escape, it is hoped, the recurrence of similar misfortune to his hernia, by the protection afforded by a truss with which he is being provided from the Hospital funds.

Remarks.—This case appears to me to present two interesting features: (1) it shows that in some rare cases, from attenuation of the hernial coverings, spontaneous rupture can and may take place from any sudden or violent physical strain, and (2) it demonstrates the possibility of recovery of the gut after protracted exposure to the external air.

THE Indian Medical Record.

16th January, 1895.

THE FIRST ANNUAL GENERAL MEETING OF THE INDIAN MEDICAL ASSOCIATION.

THE First Annual General Meeting of the INDIAN MEDICAL ASSOCIATION was held at 4.30 P.M. on Saturday, the 29th December 1894, at the Office and Library of the Association, 150 Dharantala Street, Calcutta, in accordance with Rule 27 of the Registered Rules and Regulations of the Association, and in obedience to the Resolution of the Council passed at its second meeting on the 5th December 1894, at which it was decided to ask Surgeon-Lieutenant Colonel EDWARD LAWRIE to preside, and to install the Officers and Council into their various offices by the formal vote of the Association in General Meeting assembled.

The following members were present, viz., H. H. SIR BHADVAT SINGHI, M.B., M.R.C.P., DR. LAL MADHAB MUKERJI, DR. E. W. CHAMBERS, DR. H. W. JONES, DR. K. G. SIRCAR, Surgeon-Captain H. C. HODGKINS, A. S., DR. S. O. MOSES, Surgeon-Major J. FORSYTH, S. A. S., MRS. DR. MANSELL, DR. MANMATHA NATH CHATTERJEE, DR. GUNGA GOVINDA SARKAR, DR. HURRY NATH BISWAS, DR. BEPIN BEHARI GHOSH, DR. AHMED MIRZA, DR. R. G. S. CHEW, Assistant Surgeons J. L. RAWLING SMITH, D. S. OLLENBACH, J. FRASER, G. S. O'NEAL, J. ROWLEY, D. WALLER, H. GIDNEY, R. T. RODGERS, DR. JAMES R. WALLACE and four other members who did not leave their cards, also Surgeon Lieutenant Colonel EDWARD LAWRIE by the special invitation of the Council.

The notice calling the First General Annual Meeting being read, the President, DR. LAL MADHAB MUKERJI, Rai Bahadur, rose and said:—"Your Highness, DR. LAWRIE, MRS. MANSELL and gentlemen,—At this the First Annual General Meeting of the Association, I have to express my great pleasure at seeing so fair a gathering of our members. Our membership is a large one, and this meeting represents only a very small fraction of our Association, and necessarily so, as our members are scattered far and wide over India and Burma, while those who reside in this metropolis have had their energies so much tried and their time so much occupied, that it has been a laborious task for many of us to attend this meeting. The INDIAN MEDICAL CONGRESS has absorbed our time and taxed our strength during the past four days; and this fact, coupled with the necessarily short notice of the assembling of this meeting,—due I may add to our waiting for the arrival from Hyderabad of our respected Chairman—has deprived us of the presence of many of our Calcutta brethren and other visiting members who are in town for the Congress. To all of us who are present and to our brethren all over this Empire, our gathering here this evening must and will be a source of pleasure and congratulation. It represents our society to the world at large as a duly corporate and active body. It places us, on the threshold of the great work that lies before us and confronts us with the responsible duties and aims for which our Association was first conceived.

May it be our lot to perform these duties and fulfil these aims and bear these responsibilities to the best of our ability. I will not trespass further on your attention, as we shall hear more of the Association and its work from our worthy Secretary. There now remains for me to fulfil the very pleasant duty of proposing that the Chairman of our First General Annual Meeting, who has honored us with his presence and given us this tangible evidence of his good-will and sympathy with the local profession—feelings that I may proudly and gratefully acknowledge—are shared by a very large section of the higher officials of the Indian Medical Service. An expression of this good-will and sympathy towards the local profession was publicly made by the President of the Congress, and I am sure we gladly accept these tokens of friendship from DR. HARVEY as a guarantee that the official leaders of our profession will aid our Association in furthering all its legitimate projects for the advancement of the local profession.

"It needs few words of mine to introduce DR. EDWARD LAWRIE, the gentleman whom I beg to propose to be our Chairman for this evening. He is a distinguished member of the Indian Medical Service, and a man whose name as a Surgeon and as the great and enthusiastic exponent of the principles of SYME for CHLOROFORM ADMINISTRATION, is known not only in India, but all over the world, wherever scientific medicine has a single disciple. To DR. LAWRIE as the initiator and to His Highness the NIZAM of HYDERABAD as the warm supporter of the famous Hyderabad Chloroform Commission, the medical profession and suffering humanity owe a large debt of thankfulness. The Hyderabad Commission thoroughly vindicated SYME's principles—principles I may say that have been more than vindicated by the practical experience of every surgeon in India for many years past. To many of us DR. LAWRIE is personally known, and in this large metropolis, the field of his earliest labors, his name is still a household word. We appreciate his presence with us this evening very deeply and gratefully, and I now beg to propose that DR. LAWRIE do take the chair."

This was seconded by DR. BEPIN BEHARI GHOSH, and carried unanimously with acclamation. The Chairman now called on the Secretary to read his report.

DR. WALLACE said he could not do better than present to the meeting the report of the Association that was read at the first meeting of their Provisional Council. This report proved that the first conception of the movement that had developed into the present Association, dated so far back as 1884, when the Independent Medical Practitioners' Association was set on foot. That Society did not live long, and the movement to establish an Association on a firm, permanent and extended basis was revived with the inauguration of the *Indian Medical Record* on the 1st January 1890. When sufficient general interest in the movement was aroused, the proposals for a draft prospectus for the formation of the Indian Medical Association, based on the lines of the British Medical Association, were circulated in 1892. After much consideration and correspondence with various centres throughout the country, a draft prospectus was printed in the office of the *Indian Daily News* on the 15th March 1893,

and circulated for the acceptance of the profession throughout India and Burma. It is important to bear this fact in mind to prove the priority of the origin of the INDIAN MEDICAL ASSOCIATION over any other similar movement in Bengal. The fact that this prospectus was duly promulgated on the 15th March 1893, that the original documents are in existence, and that the truth of these assertions is proved by the records of a large public printing office and by the evidence of the Committee that performed all the initiatory work of the Association, all serve to establish the claim that this Association has a priority of existence over any other movement of its kind in Bengal; while considering the catholicity of its prospectus, embracing as it does the length and breadth of the Indian Empire, and admitting into its fold, as it does, every section of our profession recognised as "qualified," I may say without fear of contradiction that it is the first movement of its kind ever started in India. Agitation of a truly constitutional type has led to our present results and we hope by a similar line of well-conducted agitation to unite the whole profession of India into one harmonious corporate body. The Secretary reported on the rapid growth of the INDIAN MEDICAL ASSOCIATION, the widespread interest it exercised, and the sound basis on which it was established, as it now numbered nearly 600 members. They were a duly registered and lawful corporate body, and after the formal installation of their Provisional Council as a permanent Council, possessed of due power to perform their duties and functions in accordance with the registered MEMORANDUM, RULES AND REGULATIONS OF THE INDIAN MEDICAL ASSOCIATION—a duty which the members would perform by their united vote this day—they would now, as their worthy President had remarked, be brought face to face with the great and responsible duties and aims which the Association was called upon to fulfil."

The Chairman, Surgeon Lieut.-Colonel EDWARD LAWRIE, now said:—

"Your Highness and Gentlemen,—I regard it as a great honor to have been invited to preside at this meeting of the INDIAN MEDICAL ASSOCIATION, and I cannot tell you the pleasure it has given me, after an absence of fifteen years, to return to Calcutta and find such striking evidence of the growth and prosperity of the medical profession during that time. This Association will doubtless become powerful for good, and I have accepted your invitation to preside at your inaugural meeting, because I have full confidence that the Association will be managed in such a way that nothing but good will come of it. There is no doubt that an Association, such as this, can represent the wants of the local profession much better than individuals can do it. I observe in the report which has just been read that the word "agitation" is employed. If I may offer a word of advice, I should recommend the Association not to stop at mere agitation, or to expect to gain anything by it alone. Representation of just wants, carefully thought out, may and undoubtedly will be of great benefit to all the members of the profession in every part of India, but I should think that the worrying of Government, however persistent, will result in no good.

* Gentlemen, India cannot do without the Indian Medical Service. It is open to all British born subjects of the

Queen-Empress, but I am told that there is a feeling among a large class of the medical community that the service is not practically open to everybody who is entitled to become a candidate for it, because the London examining boards reject many men who go up from India on what may be called "sham physical grounds." If this is true, the Association is justified in calling attention to it, but I should not feel inclined to view the rejection of even a large number of candidates on physical grounds, as necessarily in any way an evasion of anybody's rights. I knew two gentlemen who have been in India for many years, and who are both noted athletes, who were rejected for the Indian Civil Service by the London Board on the ground that they were the subjects of some defect which unfitted them for employment in a tropical climate. Again a very curious thing happened to myself. When I appeared before the Medical Board for admission into the Indian Medical Service, I had never seen a recruiting card, which is a card used to test the eyesight, having on it a number of dots arranged in various kinds of groups. When this was shewn to me, I thought the dots were letters, and after a prolonged effort to make them out I finally said: "Three Es. on the top line, and four Bs. on the second line." The examiner did not allow me to proceed further, but rejected me on account of defective vision. Directly I discovered that there were only dots on the card, I satisfied him that my vision was in no way defective. I can give you no advice as to the advisability of trying to enter the Indian Medical Service. My own opinion is that there is heaps of room in India, without reference to the I. M. S., though I am in no way advising you not to go in for it. I say there is plenty of room for lucrative practice all over India for as many men as like to take their degrees and acquire a thorough knowledge of their profession. I assert this in the face of the fact that Calcutta appears to be swarming with first class doctors. Here for example is our worthy friend, the Editor of the *Indian Medical Record*, the strong and independent medical journal which voices the needs of practitioners throughout India. DR. WALLACE is also Secretary of your Association, and this to me is sufficient proof of the esteem in which you hold him. There are dozens of other prosperous practitioners I might name, and yet I see that excellent men find it worth their while to come out from England on purpose to settle in practice in Calcutta, and they unquestionably do well. I take this fact to signify that there is ample room in our profession here and in all other towns in India, for fifty times the number of men there are at work at present.

I have had a great deal of experience of medical schools in different parts of India, and have seen something of nearly all of them, and I have no hesitation in saying that the subordinate services in this country have a bright future before them. In Hyderabad we cannot turn out the men of this class fast enough, and we are often asked to pass them out of the school months before the examinations are due. A few months after they have been in their appointments they generally return to visit their old haunts, and even in that short period, judging by their robust and rotund figures and by their gold-headed walking sticks, they shew marks of prosperity, which invariably remove all misgivings from my mind with regard to their future.

"I have already detained you too long, but before I conclude, I must proffer my warmest congratulations to the Association on having secured Rai Bahadur LAL MADHUB MOOKERJEE as its President. I am confident that no one who heard the Rai Bahadur's eloquent address on "The progress of Ophthalmology in Bengal" at the Congress the other day will ever forget it. The Vice-Presidents and Members of Council are all men of mark, and well-known far beyond the limits of the Calcutta profession, and if anything can ensure the success of the Association, the selection of officers of this stamp ought to do it. I heartily wish the Indian Medical Association a long, a prosperous, and a permanent career."

The Chairman now called upon DR. AHMED to propose:—"That the present Officers and Council of the Association be accepted as permanent." This was seconded by MRS. MANNELL, M.D., and carried unanimously.

A vote of thanks to the Chairman, was proposed by Assistant Surgeon JOHN ROWLEY, seconded by DR. MANMATHA NATH CHATTERJI, and carried with acclamation.

At the close of the meeting, DR. S. O. MOSES suggested that the Chairman be asked to intervene in bringing about an amalgamation of the Indian Medical Association with another movement, of a somewhat similar nature, urging that such an amalgamation would tend to shew a more united front and help to do good.

DR. WALLACE, the Secretary, said he cordially seconded DR. MOSES' proposal and agreed with his sentiments. He was no opponent to amalgamation. He had reviewed the position of the INDIAN MEDICAL ASSOCIATION in his Report before the Council, which would be embodied in his earlier remarks when the Report of this meeting was published. He wished it clearly understood, that, speaking for himself, he would welcome union and would gladly do his part towards accomplishing it on any reasonable basis.

DR. LAWRIE replied that he would be glad to do what he could when he was put into full possession of the facts of the case, as up to the present he knew of no other movement but that of the INDIAN MEDICAL ASSOCIATION. All the members now repaired to the Secretary's quarters for refreshments, after which the meeting dispersed.

FEVERS AND THEIR TREATMENT.

FROM the earliest ages "FEVER" has been a subject of special interest and concern to the followers of Esculapius, and this is naturally to be expected when we consider the very many and varied departures from health with which a rise of body temperature is associated. Hence it may safely be predicted that it will continue to receive the marked attention of medical men in all ages and of all nations, as on the correct estimation of its nature and indications, wherever it is found to exist, must necessarily depend the successful handling of all those diseased conditions with which it is associated.

The paper on "Pyrexia and its treatment" contributed by DR. HALE WHITE before the section of medicine of the last Annual Meeting of the British Medical Association and in the discussion that followed, as reported by the Journal of the Association, many points of vital import as to the cause and treatment of fevers and as to what a rise of

body temperature may portend or indicate were touched upon. Indeed on these matters our knowledge is still so limited and unsettled, that as DR. JAMES LINDSAY remarked at the discussion, we are still without any accepted theory of fever; and while it is generally admitted that hyperpyrexia is dangerous, it is still a matter of opinion whether a small rise of temperature is to be regarded as a friend or an enemy.

Although in the "Nervous theory of Fever" is perhaps to be found the most comprehensive explanation of the pyrexial condition, yet this is not universally applicable. The neurotic theory of fever has led DR. HALE WHITE to classify pyrexia under three heads: (1) that due to disease from damage of the central nervous system—the cortex, corpus striatum, crus, pons and spinal cord; (2) reflex pyrexia due to strong peripheral stimuli; and (3) pyrexia produced by the circulation, through the thermic apparatus, of substances absorbed into the blood.

DR. JAMES BARR drew attention to the fact that oxidation was the chief source of body heat. The heightened temperature then may be due to active oxidation of products resulting from metabolic changes caused by the fever poison; and as the oxidation of such morbid products is desirable, a heightened temperature cannot always be regarded as deleterious. Much to the same effect are the remarks of DR. R. DOUGLAS POWELL, who said that pyrexia must be considered from the microbic side also. Microbes required for their cultivation a lower temperature than that caused by the poisonous products resulting from their introduction in the system; consequently the fever induced by the microbes diminished their further productive activity. The importance of these considerations in the treatment of fevers is of course easily understood, and the remarks of physicians of such wide and extensive experience, as those who took part in the discussion on the rational management of a fever and on the dangers of some, as also on the value of therapeutical agents, are worth considering, especially as they deal with those remedial agents which have lately been much exercising the minds of our profession.

There is more or less an unanimity of opinion as to the danger always to be apprehended from hyperpyrexia, and as to the necessity for dealing promptly with this condition; for, as DR. HALE WHITE remarks, heat kills protoplasm and coagulates albumen; and by far the majority of those present at the discussion were agreed that in combating with this condition, nothing is of greater value than the application of external cold. Indeed it is particularly striking from an analysis of the remarks made at the meeting that the use of cold and the very cautious use of antipyretics is now sounded as almost the key-note in the rational and successful treatment of excessive or moderate fever. In the latter, the routine use of antipyretics is condemned, and in the former nothing has been found to give more prompt and effectual relief than the application of cold to the surface. The mode of applying cold, varies with different practitioners and with varying circumstances—the age of the patient, the disease, the climate, &c.

DR. HALE WHITE finds that in children, cold sponging may suffice to reduce an unusually high temperature; but, as a rule, a cold bath must be employed. For an adult, if the temperature be over 106°, the temperature of

the bath should be between 70 and 75°, and for children a little higher. The further directions are: lift the patient into the bath in a sheet, stir the water and when the rectal temperature falls to 100° or 101° (this is usually obtained in ten minutes) put the patient back to bed and cover him with a sheet. If collapse results, give strong brandy and water, and apply hot water bottles. A bath may be improvised, in the absence of anything better, by placing the patient on a Mackintosh sheet, raising the parts around him by means of pillows, raising the head end of the bedstead, and then pouring the cold water in at the raised end of the Mackintosh and letting the water run out at the lower end into some receptacle.

Dr. JAMES BARR was of opinion that as air and water are capable of absorbing much heat from the body, and of removing heat by convection, a properly made warm linseed poultice applied, so as to allow of free evaporation from its surface, tends to cool rapidly, to quickly absorb heat from the body, and to transfer that heat to the atmosphere, thus reducing body temperature. He was, however, quite satisfied with the results attending the treatment of severe cases of prolonged high temperature by constant immersions in water at a temperature of 90° to 98°. Drs. OSLER, R. SHINGLETON SMITH and E. MARKHAM SKERRITT were also strongly of opinion that the prompt and vigorous adoption of hydrotherapeutic measures is the best way of combating with a hyperpyrexial condition.

As to the *action* of these applications of cold to the surface in fevers, it was pointed out by several that not only do they lower the temperature, but delirium, tremor, prostration, and liability to complications were diminished by their use, so that they possibly aid in the excretion of toxins, as proved by the experiments of ROQUE and WEIL that in cases of typhoid fever treated by cold baths the elimination of toxic products was enormously helped and increased. Dr. JAMES BARR was of opinion that the beneficial results of cold applications may be due to their rousing up the nervous system to better regulate heat-production; while Dr. A. J. BENTLEY of Cairo remarked, that as the wet pack and the application of ice to the abdomen in the treatment of cholera relieved restlessness and set up reaction, cold may act as an antidote to the cholera bacillus.

With regard to *ordinary pyrexia*, Dr. WHITE maintained that as it has not been proved that this condition is in itself harmful—and in fact by some *e.g.* CANTANI is regarded as beneficial at times—it is unwise to treat it as a symptom, as our treatment may do more harm than the disease. In ordinary pyrexia we should therefore not be too anxious to reduce the temperature for the following reasons: (1) Some of the specific micro-organisms manufacture two substances, one pyrogenous and the other causing fatal symptoms. By treating the pyrexia the second is still left active, although the patient may appear better. The reduction of pyrexia then may give a false sense of security; (2) antipyretics do great harm in the early stages of febrile diseases by abolishing an important aid to diagnosis; and (3) lowering the temperature may impair the immunity which an attack of a specific fever often confers; as the obtaining of immunity, such as that afforded from small-pox by vaccination, often entails pyrexia. The pyrexia should then not

be treated unless there be reason to believe that it is diminishing the activity of the heart or nervous system. In the pyrexia of typhoid if the temperature be over 102.5, cold sponging, the cold pack, or the cooled tepid bath may be used with benefit. He thought the cold bath undesirable, as the shock is too great. Dr. BARR and Sir THOMAS GRANGER STEWART also were in favor of cold compresses and wet packs in moderate pyrexial conditions, while Drs. OSLER and FRANK POPP advocated the employment of the cold bath in typhoid. It was thought that the pyrexia of phthisis is best left alone, and that the use of antipyretics in its relief was quite useless and unsatisfactory.

With regard to *drugs* Dr. SNOW remarked that calomel, the sheet anchor of a former generation in all cases of fever, is not without its virtues, partly by purifying the *primæ viæ*, and partly by being converted into mercuric perchloride which is hostile to microbes. Dr. F. ROBERTS drew attention to the necessity for using simple remedies, such as the old saline mixture, Dr. W. KEMP of New Zealand considered aconite very useful in fevers, especially in children. Dr. TYSON advised the use of aperients, and that the diarrhoea sometimes accompanying pyrexia be not checked. The value of quinine as an antitoxin in some pyrexial conditions was referred to. Dr. E. SKERRITT used it in thirty or forty-grain doses in adults, this quantity being given as one dose or in two with an interval of half an hour; and as its effects are very slowly developed, it does not cause collapse, and its influence extends over a longer period than that of any other antipyretic. Dr. DOUGLAS POWELL occasionally combined quinine with the salicin class of remedies; while Dr. A. BENTLEY found a mixture of quinine and sulphate of magnesia most useful in bilious remittent fever. Mrs. ELIZABETH ANDERSON, M.D., found that anaemia may be accompanied by pyrexia which is rapidly relieved by iron and rest in bed.

We have reserved for the last the expressions of opinion on the class of antipyretics so very commonly; and we fear very injudiciously and deleteriously, made use of now-a-days—antifebrin, antipyrin, phenacetin, &c. From all the foregoing, it must be conceded that their administration in ordinary cases of pyrexia is to be condemned. Dr. WHITE says that these agents are losing favor with the profession, as they produce cardiac depression and cyanosis, and ROGUE and WEIL believe that they do not help the extraction of poisons. Dr. LINDSAY has found no permanent benefit from their use in a typhoid case, while Dr. SKERRITT had long given up the use of antipyrin in this disease, as it has been known to produce the most dangerous depression.

Dr. TYSON is of opinion that aperients in many pyrexias are a more rational treatment than the now common use of phenacetin, &c. Dr. KEMP did not find antipyretics of much use in enteric fever, and Dr. MAHOMED looks upon antipyrin as a dangerous drug. The only opinions in favor of the drugs in question were the following:—Dr. SHINGLETON SMITH had never seen any harm from the efficient but not excessive use of phenacetin. Dr. STEWART trusted to cold sponging, &c., and the continuous use of antipyretics. Dr. R. HEATH was able to mention but one case with a temperature of 106.2° in which forty-grains of antipyrin given in ten-grain doses every four hours was used with

the best result, and Dr. BARTLEY thought that in influenza the most successful mode of treatment was by antipyrin combined with salicylate of sodium, ten grains of each, every four hours. This brings the temperature to normal in twenty-four hours.

In reference to the treatment of fevers, history appears to be repeating itself; and the profession inclines to go back to the simpler remedies of former years, and to regard with disfavor or to adopt with diffidence the mass of synthetical remedies which, while they do honor to the science of chemistry, are making our extra pharmacopoeia a ponderous volume of drugs of very questionable utility.

OUR RECORD FOR 1894.

ANOTHER year of existence, another year of success, of progress, and of fresh achievements. Such is our record for the year that has just closed; and we may be pardoned if we evince a certain amount of jubilation over such a result. We feel it our duty to offer to our numerous and generous contributors our hearty thanks for the kind help they have accorded us, and by which we have been able to make the *Record* increasingly appreciated. Our helpers have been many, and we would hope that the services in India will, by their continued and augmented literary aid, shew that they fully realise how much can be hoped for and effected by supporting a journalistic organ. Among the various developments and healthy signs of our generation is to be reckoned the increasing demand for medical literature, which demand has in recent years, brought into existence in this country an increase of medical journals. The various ways in which journalism can benefit the profession are too well known and acknowledged, and the enumeration is certainly unnecessary. Admissions and acknowledgments can however avail naught; but determined and well sustained co-operation is indispensably necessary for our progress and advancement. We have before this distinctly declared, and we hope have proved, that we labor in the interests of the profession in this country in particular; that is, while we are concerned pleasurably in everything that will make our profession better and nobler in every way all the wide world over, we have an especial interest in whatever favors our cause in this country. The medical worth and intelligence of India may be regarded as a hidden light—a light shrouded and shaded by a thick screen of western jealousy and cynicism—and the sure and practical way of breaking through the obstruction is for the men of the country to give to the world the worthy literary contributions which we are assured they are fully capable of giving, and also by powerful and determined union and association. In both these respects we have had much cause for gratification in the year 1894. Our appeal, made somewhat in the same terms as at the close of 1893, to the members of the local profession to shew what they are worth, what they have done, and can do, has been met with a response fully evidenced in our columns; and the fact of the INDIAN MEDICAL ASSOCIATION having become a *fait accompli*, gives a strong guarantee of better days for our local professional brethren. The establishment of this association, is an item of special gratification among our labors of the past year, for we feel sure that it will mark an era in the

history of the profession in India. In the past number that have joined it, and in the readiness with which so many have sought enrolment, we have evidence not only of such an association being a crying want, but that our local brethren have learnt the value of UNITY. The closing months of the year 1894 saw the association a legally constituted and registered body, and the 29th of December last, marks the first Annual General Meeting of the Association. It was held under the presidency of Surgeon Lieutenant-Colonel LAWRIE, than whom there is probably to be found no one who is a stauncher friend or readier helper of the local profession.

Yet another achievement which by the help and support of our readers and contributors we have been able to effect, is the enlargement of our Journal from the 1st of January last; and this, of course, means more literary help to us, more interest in clinical work, by willing contributors, and more medical reading and information to subscribers. We regard as the most important event, not only of the Indian *Annus Medicus* 1894, but in the life history of the profession in India, the meeting of the Indian Medical Congress. Nothing can be more portentous of good. Although we had occasion to remark that this gathering, the first of its kind in this country, was unfortunately characterised by no small amount of invidious party feeling, we feel sure that time will destroy all sectarian prejudices, and that these gatherings will result in a *approachment* of the different services and branches of the profession in India.

There has been no change of note in the Commissioned services of the country. With the Army Scheme being put in regular working however, and with the unification of the Commissioned Medical Services, there are sure to arise conditions and circumstances prejudicial to individual interests, not the least perhaps of which will be that special appointments in the different commands and presidencies will be very uncertain expectations indeed. The Warrant Medical Services have been placed in part possession of what should in all reasonableness be accorded them by the grant of the designation of Assistant Surgeon; and relying on the promises of a great and honorable Government, we may hope that ere long a more substantial consideration will be given them by their pay and pension being raised. We are sorry to note that there are a few who think that this class of public servants are not underpaid; but the Government of India, it is highly satisfactory to reflect, holds to an opposite opinion. The wars and expeditions of the past quarter of a century have made the lives of military medical subordinates literally a very struggling existence. Their lot in the field, and that of the poor Military Hospital Assistants also, is one of the hardest, if not positively the worst, of those engaged on active service. The very inadequate establishments of the subordinate military medical services, and their consequent over-work, both in garrison and field employ, has seriously shattered the health and constitution of many of them, and have certainly taken a good number of years out of their natural brief term of life. It may well be asked by them whether life is worth living in the department for the small remuneration given in a service which generally ends in impaired constitutions and curtailed existence.

The grievances of the Civil Medical Services—of Assistant Surgeons and Hospital Assistants—have been well and prominently ventilated in our columns, and there is every reason to believe that they will soon receive the mode of consideration which has long and persistently been withheld. We do not blame the Government in this matter. They have for years past been kept blind to the merits and usefulness of these civil medical officers. Within the past few years, however, the grievances of the Civil Medical Services have been acknowledged, and we hope that this year of grace, upon which we have just entered, will be marked by a re-construction of the Civil Medical Services of the country and in an appropriate recompense to our friends the Civil Assistant Surgeons and Hospital Assistants, both in the remuneration and status of their long neglected services.

We would again wish each and every one of our contributors and readers a very HAPPY NEW YEAR.

COMMENTS AND NEWS.

DR. LAWRIE ON HAFFKINE'S CHOLERA INOCULATION.

It will be interesting at the present time when so much attention is being publicly called to the subject of cholera, to reproduce Surgeon-Colonel EDWARD LAWRIE'S criticism of HAFFKINE'S system of Cholera Inoculation, delivered before the Indian Medical Congress. Dr. LAWRIE said:—

"MR. PRESIDENT AND GENTLEMEN,—We must all welcome any proposal or measure which has for its object the prevention of cholera, and admire anybody who, like M. HAFFKINE, endeavours to stamp out the disease in the energetic way he has done. But we must not allow our admiration of M. HAFFKINE to obscure our vision or consideration of actual facts, and I venture to bring to your notice a few facts with regard to his inoculations for cholera, for the purpose, let me assure you, of furthering our progress in the direction in which M. HAFFKINE is working.

"M. HAFFKINE has stated a well-known fact, animals cannot contract cholera. The question then is,—What condition is produced in animals by inoculation with the attenuated decoctions or cultivations of the comma bacillus? It must be some form of septicæmia, not necessarily infective; and you must keep in mind that almost all forms of septicæmia may be in their nature either very mild and harmless or very severe and uncontrollable. We know that in septic poisoning in man or in animals, diarrhoea is often a prominent symptom, and is also a common cause of a fatal termination of the disease. The vexed point that has to be determined is whether septic poisoning in any form is ever curative or preventive of other diseases. Three examples occur to me in which it has been proved to exert a curative action. It was long ago discovered that in indurated ulcer of the leg accidental attacks of erysipelas caused the thickening to disappear, and the ulcer healed up; and this led to blistering in ulcers of this kind as a safe and effective imitation of the unsafe erysipelas. The second example was brought to my notice only this morning by Surgeon Lieutenant Colonel J. O'BRIEN. A patient under his care for compound fracture of the leg of several weeks standing got general dermatitis, and when the dermatitis subsided, the wound was found to be so much improved that it forthwith commenced to heal and speedily got well. The same kind of effect was observed in the KOOK cure for tuberculosis. The local effect was in certain cases beneficial, but the constitutional effect could not always be kept within safe limits, in fact the case showed itself to be dangerous.

In the same manner we now have HAFFKINE'S inoculations brought forward as a cure or preventive for cholera. These inoculations produce a period of illness, generally slight and harmless as compared with that produced by KOOK'S tuberculin but, like that, a form of blood poisoning. The question next arises,—Is septicæmia in any form whatsoever a preventive of cholera, and if so, to what extent? If mild attacks of blood-poisoning or septicæmia can be proved to protect entirely or to any appreciable extent against cholera, there will be some ground for claiming protection to the same extent by HAFFKINE'S inoculations or vaccinations. But nothing of the kind has been proved as yet: in fact the evidence so far is all the other way. It appears to me that cholera is much too complicated and serious a condition to be accounted for by a cause so simple and easy to deal with as the comma bacillus. Moreover, bacteriologists themselves are not agreed as to the identity of the microbe, and cholera cases are certainly met with everywhere in which the comma is not even a concomitant of the disease. Lastly, in order to make out the semblance of a logical case for the comma bacillus, M. HAFFKINE is bound to shew that it is present in the organism prior to the commencement of the symptoms of the disease it is said to cause. There is little doubt cholera may be driven away by a pure water supply. What it is in dirty or infected water which gives rise to cholera is a point of the last importance, and I for one am content to leave it to bacteriologists to discover."

HONORS TO INDIAN MEDICAL OFFICERS.

It is remarkable, and most conspicuously so, that year after year goes by and the HONORS LIST of the *Government of India Gazette*, while it contains the name of many a happy and deserving officer of the Civil and Military services, medical officers are left without the reward of decoration for their work and worth. It was expected that the unusual and important occasion of the Medical Congress would have been marked by some recognition of the medical profession by the Government in some special manner, and it was hoped that some of the leaders of the profession intimately connected with the medical administration of the country would have been decorated in the recent Honors List. The heads of the Survey, Public Works, Revenue, Legal and other departments of the State in India, hold the distinguished honor of knighthood, and rightly so. Their burdens and responsibilities are great, and their position is worthy of the respect and honor that are paid to them. While admitting these facts, the claims of the medical profession, great as they are to the highest and best consideration of the State, are conspicuously neglected. We expected to see Surgeon Major-General W. R. RICE made a Knight of the Star of India of which he holds a Companionship, and how fittingly would the honor of a Companionship have fallen upon the worthy President of the Indian Medical Congress—an officer whose public services command the kindest appreciation of the Government. Then we have Surgeon-Colonel HOOVER, who succeeds Sir JOSEPH FAYRE, without even a C. I. B., and many other splendid officers of our profession, some retired and others in active service, whose merit and faithful work have long since earned some tangible mark of public esteem, all doomed to disappointment. It is not yet too late to consider the case of the DOCTORS, Generals, Judges, Engineers, Lawyers, Politicians, Financiers, Philanthropists, have all obtained a place for their representatives on the New Year's Honors List. Will the Government not correct its many sins of omission and bestow its gracious tokens of appreciation on the medical profession? LORD ELGIN eulogised the State medical services in a very estimable manner in his recent public utterances, and may we not hope that His Excellency will support his words by acts, the doing of which, will honor the Government of India as much as it will the Medical Services.

OCCUPATION AND EYESIGHT.

We abstract from the *Lancet*:—MR. SIMEON SNELL, Ophthalmic Surgeon to the General Infirmary, Sheffield, read a paper at a recent meeting of the British Medical Association on the relations of some occupations to eyesight. His conclusions are that the *biacids* of carbon used in the vulcanisation of India-rubber causes amblyopia. Di-nitrobenzol, used in the manufacture of explosives, induces amblyopia or dulness of vision, chiefly in those engaged in mixing or grinding the material. GALEZOWSKI is of opinion that the inhalation of nicotine powder by those engaged in the manufacture of tobacco causes visual disturbances in the persons so employed; but MR. SNELL's enquiries make him concur in the opinions of MESSRS. SHEARS, C. LEE and of DR. DOWLING, all of whose observations have been extensive in this direction, that visual troubles do not affect persons engaged in tobacco factories. MR. SNELL's observations do not, moreover, bear out the opinions of MR. PRIESTLEY SMITH and VALUDE, that lead-form manufacturers suffer from dulness of vision. File-cutters suffer from saturnine amblyopia. The statement made by some observers that glass-blowers often suffer from cataract is not confirmed or supported by MR. SNELL, who finds, however, that a man can look with more or less ease at a metal in a furnace up to a temperature of 2000°F; hence in cast-iron furnaces as the heat of the metal is from 1800° to 2000° the men take no precautions; but persons working at molten steel (temperature being from 2700° to 2800°) have to wear dark blue glasses to protect their eyes. In none of these has MR. SNELL been able to detect any deep or superficial eye lesion as a result of the light and heat. The light employed in electric welding—about 8000 candles power—causes sharp conjunctivitis with great pain and lacrymation; and if it be allowed to enter the eye, optic neuritis with retinitis may occur.

CHOLERA MORBUS. A REQUIEM OVER THE LUCKNOW EPIDEMIC.

SAYS *Lloyds' Weekly*:—A soldier (PTE. J. CONROY, First Battalion East Lancashire Regiment, asks us to find space for the following lines, and the pathetic nature of the story which they reveal commands immediate attention as it concerns the 98 men of his regiment who lost their lives in the cholera epidemic of July and August 1894 at Lucknow and Ekraill:—

Why, lads, you look grave and dejected; the smiles have all gone from your face,
Something dreadful I'm sure must have happened. Come tell me what has taken place?
And where are the lads I remember that once formed a jovial throng?
I miss their familiar faces; I'm sure something must have gone wrong.
The story's a sad one to tell, sir—God help me, I scarcely can speak,
As I think of their places left vacant, my heart it feels ready to break.
One morning we woke from our slumbers, to hear news that with horror did fill:
The cholera had broke out amongst us. Two comrades were carried off ill.
We knew then that death hovered round us; we waited in silence and dread,
When some one came in then they told us; poor Kenny and Johnson were dead!
It was then we were ordered to camp, sir, on the Brigade square that's not far away;
It is used by the garrison at large, sir; and there we were forced now to stay,
I assure you it was not so lively, with mousoons it just looked a swamp;
The poor men very soon were complaining of sickness, diarrhoea and cramp.
The doctors—like heroes they worked, sir, their efforts seemed of no avail,

It was then the poor *Thirlwall* was ordered to move camp to a place called *Kokrah*.
Surgeons Thompson, McDowell and Pilcher, with Surgeon Withers—by all they are blest,
But it was not in men's power to save them, and soon they were laid low at rest.
The scenes on the camp were heart-rending, though to cheer our men we all tried,
We all did our best to attend them, but they weakened and sickened and died.
It was then that we found there were heroes, for deny it I'm sure no one can,
For no assistant surgeons worked harder than O'Donoghue, McCarthy, and Mann.
By no means forgetting the others, whose names you have all heard, no doubt:
Mr. Holmes, Mr. Atwell, and Murphy were continually moving about;
The Reverend Father Petronius—God bless him—he always was there,
Like an angel of mercy from heaven, his presence was every where.
Now brave lads of humbler station in life's battle, "Before you I'll bring;
Their goodness cannot be forgotten; their praises all true men should sing.
When the news that their comrades were dying these lads in their tents chanced to hear;
Although on their beds they were lying, to nurse them they soon volunteer.
Such bravery will not be forgotten—their praises they ring far and near,
I am happy to find that such brave lads, belonged to the East Lancashire.
There was Kelly, West, Lundy, and Conroy, Brotherton, Dunn, Glenn, and Maclear.
With Atkinson, Warring, and Lovvatt, and Patterson, likewise was there;
There was Partington, Harris, and Wilson, Craig, Ogilvie, Walker, and Knowle,
But the first night of brave Walker's duty, the angels bore off his poor soul;
The night of the third day of August would have filled any heart with a fright,
For to hear the loud peals of the thunder quickly followed by flashes of light;
And the rain that was falling in torrents rushed in under every man's bed,
While the lamps dimly burning above us showed the faces of dying and dead.
We could see the still forms of our comrades borne away in the thunder and rain,
For thirteen brave lads fell asleep on that night, who never will waken again.
It was sad to stand by their beds there, and know that no power on earth
Could grant them their last dying wish, sir; one glance of the land of their birth.
And to hear their weak voices keep calling, for a father, a mother, or wife,
While some from their God were imploring, to forgive them their sins of past life.
When the news is heard in Old England, it will cause many a heart grief and pain.
As they think of the bright, happy faces that in this world they won't see again.
And the heart broken parents at home there, God help them to bear this sad blow
As they think of their sons that are lying on the far distant plains of Lucknow.

BENGAL CHEMICAL EXAMINERS.

It is very gratifying to record the public satisfaction that is generally felt all over Bengal, and in Calcutta particularly, at the excellent and most efficient way in which the present work of chemical analysis and medico-legal examinations is being carried out by the Chemical Examiners' Department of the Bengal Government, in which Surgeon Captain J. F. EVANS, M.B., I. M. S., Professor of Chemistry and DR. CHUNEE LAL BÖSE, F. C. S., are the officers concerned.

SPECTACLE SELLERS AND THEIR COMMISSIONS TO DOCTORS.

It has been brought to our notice that a firm of spectacle sellers in Calcutta, thrives on a monopoly of prescription orders for glasses, which are given under the distinct understanding that a commission of 30 per cent. be paid to the prescribers by the said firm, while other firms equally well equipped, are denied the patronage of the public, because they refuse to stoop to a system of granting commission which they declare is tantamount to robbing their customers. We would draw the attention of the prescribers to the recent ruling of the General Medical Council of Great Britain, and we would warn the firm that this practice must cease, as no matter how tempting the bait, the system is a fraud on the public, as it entails the payment of higher prices by patients, who are compelled to buy their glasses from the firm the prescription is sent to, and of necessity the so-called *opticians* must make good their own profits by adding the commission to the prescriber, to the sale price of the spectacles and this entails a payment of about 50 per cent. more than the honest selling price of the glasses. We would specially ask the prescribers to discontinue and discountenance any further transactions of this sordid nature, which sinks the medical profession to the level of a very questionable trade.

THE DOCTOR AS A MAN AND A COMPANION.

THE following passage from MR. JAMES PAYN'S "Gleanings of Memory," now appearing in the *Coruhill Magazine*, will be interesting to members of the medical profession. He says:—"Upon the whole, and for 'a scratch' companion, I prefer a doctor to a man of any other calling. He may not be very good as a conversationalist, but he is rarely very bad, like a cheroot. He has a genuine experience of life, and has seen down to the depths of it; a sick man does not attempt to deceive his doctor, or put the best face on his character, as he does with a priest. Moreover, what is very unusual, your doctor knows more about you, professionally at all events, than you know about yourself. He does not tell you about it, it is true; not a word of that aneurism you carry about with you, and which will some day kill you in half a minute, but your consciousness that he may possess such knowledge makes him interesting. The best suggestions I have had made to me for plots for my novels have come to me from doctors, to whom I have also had cause to be grateful for many things."

BRASS FOUNDERS' DISEASES.

BRASS founding is said to cause various forms of disease, viz., gout, chronic nephritis, progressive paralysis of legs, tremor, muscular wasting, and locomotor ataxy. A group of symptoms spoken of as brass founders' ague has also been noticed. "The fit of ague is ushered in by languor and depression, then prostration with pallor, cold sweats, and chills, that even may amount to rigors, with chattering of the teeth, precordial anxiety, headache, nausea and muscular pains. The onset of vomiting arrests the symptoms and usually is followed by sleep, from which the patient arouses almost well" (ARLIDGE). We learn from the *British Medical Journal* that the Home Secretary intends therefore to schedule brass casting and mixing as unhealthy industries; and proposes rules aiming at cleanliness of person and workshop, ventilation, provision of respirators while actually casting, and the prohibition of eating where casting and mixing are carried on.

BLACK-MATING AN INDIAN PHYSICIAN.

THE case in which the Raja of Nattore was charged with extorting a promissory note from DR. GANGA GOBINDA SARKARA, who had been in his employ, has ended in the conviction of the Raja, and his being sentenced to six months' rigorous imprisonment with a fine of Rs. 25,000, Rs. 6,000 of which, if realised, is to be paid to the complainant as com-

pensation. MR. L. PALIT, the officiating Sessions Judge of Boalia, who tried the case, said that he was unable to accept the opinion of the two European assessors who were in favor of acquittal. An appeal has been admitted by the High Court of Calcutta, we are sure our brethren will heartily sympathise with DR. SARKARA in his troubles, for unquestionably the prosecution of this case has entailed on him much anxiety and expense. He has now to face the burden of an appeal, in which we sincerely hope he will prove successful. We would be glad to see a fund raised for aiding DR. SARKARA in his troubles. Our Manager would gladly forward all subscriptions received and they would be duly acknowledged in the *Record*.

INDIAN MEDICAL ASSOCIATION ITEMS.

THE second meeting of the Council of the Indian Medical Association was held at the office of the Association at 6 P.M., on the 15th December 1894. Present: DR. LAL MADHAB MUKERJEE, President (in the chair), DR. J. G. ANDERSON, K. G. SIRCAR, H. W. JONES, M. L. DUTT, H. C. HODGKINS and J. R. WALLACE. Items of business:—(1) The notice calling the meeting was read, (2) the minutes of the last meeting were read and confirmed, (3) date of starting *old* Association corrected from 1886 to 1884 (first pamphlet of old association placed on table and filed); (4) date of First Annual General Meeting fixed for Saturday, 29th December 1894 at 4-30 P.M.; (5) meeting to be held at the office of the Association, (6) Secretary to prepare programme for meeting and to make all needful arrangements for the same, (7) resolution to make present Council and Officers "permanent," to be put to meeting, (8) that Surgeon Lieutenant Colonel EDWARD LAWRIE of Hyderabad be asked to take the chair at the First Annual General Meeting, (9) that after receiving DR. LAWRIE'S consent, notices for the meeting be issued on post-cards.

The Annual Meeting took place and a brief note of the same appeared in the last number of the *Record*, a full report of the same appears in this number.

A Sub-Committee consisting of DRS. MUKERJEE, SIRCAR, HODGKINS and WALLACE met on Friday the 11th January, to consider the subject of the grievances of Civil Assistant Surgeons and Hospital Assistants. It was decided, after a discussion of the matter, that the President and the Secretary do forthwith prepare a report on the subject for the Council, in view of the early submission of a representation to Government.

NEW MEMBERS OF THE INDIAN MEDICAL ASSOCIATION.

WE have pleasure in publishing the names of the following gentlemen who have joined the Association since our last issue:—

John E. Panlthy, L.E.C.P., Lond., L.R.C.S. Edin., Resident Surgeon, Chaudhry Hospital, Calcutta.

J. Dolby, Asst. Surgeon, I. M. S., Civil Surgeon, Bhamo, Up. Burma.

P. H. Rodrigues, Asst. Surgeon, I. M. S., Medical Officer, Hill Fort, Satara.

T. Maduranayagam Pillay, C.M.S., Hospital Assistant, 22nd Madras Infantry, Secunderabad.

W. A. Boucher, Asst. Surgeon, I. M. S., Station Hospital, Umballa.

Robert Brown, C.M.S., Asst. Surgeon, I. M. S., Medical Officer, E. B. & Ry., Sara Ghat.

Medical men and women in all parts of India and Burma who desire to take a share in aiding the advancement of the Indian Medical Association are cordially requested to write to the Editor of the *Indian Medical Record*, and he will gladly send them blank membership forms and prospectuses. We are glad to find many willing Volunteers.

REWARD OF THOROUGHNESS.

WHAT'ER thou dost, do well—it may not stand
An hour, it may for centuries endure,
But thou shalt have performed thy Lord's command,
And thy reward shall be for ever sure.

It may not be a palace thou dost rear,
It may be but a cottage for the poor;
No matter, 'tis the Lord's; be of good cheer,
Palace or cottage, thy reward is sure.

Here thou must learn to work: earth is God's school;
Let not thy hours in idleness be spent;
Bow thy stiff neck, thy stubborn spirit rule,
What thy Lord sets thee, do, and be content.
When He has tried and fully proved thy worth,
Found thee obedient, diligent, and true,
Then He will take thee from his school of earth,
And in His heaven-world give thee work to do.

—Oliver Wendell Holmes.

AVERAGE LIFE OF PHYSICIANS.

ONE of the most curious statistical records compiled during the nineteenth century is that by DR. SALZMANN, of Essling, Wurtemberg, regarding the average duration of life among practitioners of medicine. He found, on going over the ancient records of Wurtemberg, that in the sixteenth century the average duration of life among medical men was but 36.5 years; in the seventeenth century, 45.8; in the eighteenth, 49.8; and that at the present time they reach the favorable age of 56.7.

It appears in the compilation, that DR. SALZMANN ascribes the great increase in longevity to the disappearance of the "black pest," the introduction of vaccination, and the great diminution in the number of typhus epidemics—representing three classes of disease which formerly decimated the medical population.

SCARS AND NEURALGIAS.

HANS VON BULOW, the eminent pianist and conductor who died in Cairo in February last, had for years been a martyr to maddening headaches. In accordance with his often-expressed wish, after his death, PROFESSOR KAUFMANN, of Cairo, who performed the *post-mortem* examination, extracted the brain, and sent it to a German physician for examination. It now appears that the surface origin of two nerves leading to the scalp was imbedded in a scar, left by an attack of meningitis in early youth. Whether this scar can be held responsible for the great artist's many eccentricities must remain an open question.

CALCUTTA MEDICAL COLLEGE HONORS LIST.

THE recent Test and Honor Examinations of the Calcutta Medical College were attended with the following results:—
Hygiene:—Gold Medal, H. L. O. FLEMING (Military); 1st certificate J. E. L. CHINAL and A. E. CLARKE (both military); 2nd certificate, Syam Lal Barat. *Dentistry*:—Gold Medal, E. S. Pushong (military); 1st certificate, Satyendra Nath Sen; 2nd certificate, Satya Saran Mitra. *Medical Jurisprudence*:—Gold Medal, Susil Chandra Bhattacharya; 1st certificate, J. J. McDonald (military); 2nd certificate, Kali Mohan Sen; 3rd certificate, Miss L. Phillips.

HONORS FOR THE LOCAL SERVICES.

The title of Khan Bahadur is bestowed on Muhammad Husain, Senior Hospital Assistant, Bengal; the title of Rao Bahadur on Trichinopoly Venkataswami Niamagani Pillai, Senior Hospital Assistant, Madras Sappers and Miners and on Camaisapuram Lutchmiah Nayadu, Senior Hospital Assistant, 2nd Madras Lancers; the titles of Rai Bahadur on Dr. Kailas Chunder Bose, late President of the Calcutta Society, and Lala Radha Kishen, Assistant Surgeon in the Punjab. All very deserving men indeed.

A FRAUD AND A SLANDERER.

DR. E. F. CASTLE and MR. W. M. JONES brought an action for slander against a bone-setter farmer, whose certificates bore the above calumny as affix, because when attending to a colliery boy who was treated by the plaintiffs for a "crushed arm," he said that the boy had been improperly treated by the plaintiffs, and telling the boy that he would be a cripple for life unless the limb was broken afresh and reset, remarked: "What a lot of those men's work I have had to put right." The suit was heard at the West Riding Assizes, where the jury assessed the damages at £80 and the evidence disclosed that the mystic letters following the name of the defendant bone-setter, who had never attended College nor received any surgical training meant Registered Chemist, Member of the Pharmaceutical Conference and Veterinary Surgeon, "R. C., M. P.C., V. S."

SHORT ITEMS.

Veterinary-Captain Joshua Arthur Nunn, D.S.O., F.R.C.V.S., Army Veterinary Department, Principal, Veterinary College, Lahore, has been made a C. I. E. We congratulate Captain Nunn, and are heartily glad to see the veterinary profession thus recognised.

The new Dufferin Hospital at Amraoti, in Berar, which has just been constructed at a cost of about Rs. 30,000, has been formally opened. Miss Trewhy, from the Lady Lyall Hospital, Agra, has been selected to take charge.

It has been decided that Surgeon-Colonel Cleghorn shall succeed Surgeon-Major-General Rice, when the latter shortly vacates his appointment as Surgeon-General with the Government of India.

Surgeon-Major R. W. S. Lyons, M.D., has been appointed to act as Professor of Medicine and Clinical Medicine and Therapeutics, Grant Medical College, during the absence of Surgeon-Major R. Manser, M.D.

Professor Gairdner, of Glasgow, has been re-elected to the Presidential chair at the Edinburgh Royal College of Physicians. Professor Simpson of Edinburgh has again been appointed Vice-President.

The services of Surgeon-Captain C. Duer, M.D., F.R.C.S. I. M. S., Bengal, stationed at Dhubri, in Assam are replaced at the disposal of the Military Department.

At the examinations to be held next month in London twelve commissions in the Army Medical Staff and eighteen in the Indian Medical Service will be competed for.

Dr. K. G. Kar, L.B.C.P. & S. Edin., a practising physician, of Calcutta, has been appointed Examiner in *Materia Medica* at the next L. M. S. examinations of the Calcutta University.

Surgeon-Lieutenant Seton, who was wounded a few days ago at Kaniguran, is doing well. He was shot in the knee and fell, dislocating his thumb.

Brigade-Surgeon Lieutenant-Colonel J. C. G. Carmichael, M.D., I. M. S., P. M. O., Presidency District, proceeds home shortly on furlough.

Surgeon-Major Edward Ferrand, I. M. S., has passed the examination for the F. R. C. S. of England.

Surgeon Captain Edward Gibson, M.A.S., (retired) has been appointed Chief Sanitary Inspector of Bangalore.

Dr. M. G. Deshmukh is a candidate for the new Bombay Municipal Corporation.

There are 420,000 people in France affected with goitre.

OUR LONDON LETTER.

(From our own Correspondent.)

A NEW battle ground (this time on bacteriological principles) is being fought over as to the method of treatment which Professor BEHRING terms "*blood serum*" therapy as applied to one disease, namely, *diphtheria*. The method of preparing anti-diphtheritic serum, which most commends itself to English medical men, is that of Dr. ROUX of the Institut Pasteur, Paris. So far a series of cases has been published in various journals throughout Germany, France, Holland, England and Italy (ROUX) amounting to about 1,400 patients treated by injections of anti-diphtheritic serum or antitoxin diphtheria, as it is termed by BEHRING, in doses from 1 c.c. (m.xv) to 30 c.c. (3viii); the average mortality of these cases being about 20 per cent. on the total number of patients infected.

The most fatal cases being those known as "*mixed infection*." Those affected with "*pure diphtheria*" alone showed a mortality of about 5 per cent., as shown by the cultivations made from the false membranes coughed up or obtained by the point of the spatula when examining the throat, and thereafter inoculated on sterilised serum in a test-tube, where the various colonies of bacteria can be detected growing, say 24 hours after the virulent bacillus of KLEBS and LOEFFLER is placed in contact with the culture medium. Serum is being manufactured rapidly in England by two or three eminent bacteriological teachers, or at any rate under their supervision. We have not yet accepted the treatment as a specific, but it bids fair to prove so in the near future, despite gloomy anticipations in a few quarters, and mutterings about the fate of KOCH's "*Tuberculin*," which latter drug has at least proved itself useful as a test or as confirmatory of a diagnosis of

tuberculosis. Very curiously too, it may be noted, that Dr. BEHRING was associated in his discoveries with Dr. KITASATO, the well-known Japanese bacteriologist, the discoverer of the bacillus of Bubonic Plague. With Dr. ROUX of Paris is associated Dr. YERSIN, who also studied and described the plague bacillus, both working simultaneously during the late plague epidemic in Hong-Kong. This fact may draw the attention of your readers and further interest them in the late investigations into seropathy, especially as Bubonic Plague has visited India on various occasions, and more remarkable still, if true, as BEHRING hints that the symptoms following the bites of venomous serpents may be found amenable to injections of "blood serum." How this will turn out remains to be seen! Many subscriptions have been collected throughout Germany, France, &c., for the establishment of laboratories, wherein the bacteriological work, such as cultivation of the diphtheria toxins, can be carried out previous to immunising horses from whom the anti-diphtheritic serum or antitoxin is to be obtained. These horses are first examined by skilled veterinarians, who have to pronounce them free from disease before they are made use of; they also test them for glanders by hypodermic injections of mallein. These precautions should satisfy even the most prejudiced minds, who are wont to talk about *omne ignotum pro nobili*, when discussing the merits or demerits of a new remedy, or any other invention which cannot be understood at half a glance. The anti-diphtheritic serum, as a remedy for diphtheria, rests on the basis, at any rate, of certain established physiological facts worked out, as to the properties and physiological functions of blood serum by such authorities as BACHNER, HUXLIN and others, forming a famous list of experimenters. The experiments of BEHRING are confirmed by those of KITASATO, and Drs. ROUX and YERSIN working together have corroborated all these facts in detail and added others to them. Dr. ROUX, in spite of his great contributions towards BEHRING's ultimate discovery of antitoxin-antidiphtheritic serum (ROUX), although with the true modesty of an earnest and devoted scientist, awards the greatest need of praise to BEHRING, when he states that BEHRING placed the crowning stone of the arch of this series of discoveries, i.e., when he utilised the serum of immunised animals in the treatment of diphtheria. A certain evening newspaper in London, with a large circulation, has published two or three letters from correspondents decrying the antitoxin treatment of any disease; the first denominating the serum a filthy remedy; the second casting semi-scientific aspersions, on the method by stating all the weak points of the method in an unscientific basis, and distorting, for the purpose of exciting popular ridicule, those points which have been left open in the scientific papers on the same subject, and in no wise admitting any of the established and confirmed and scientific medical and therapeutic facts of which we, as medical men, must be cognisant. It seems to me that these subjects should not be provided as pabulum for popular superstition and be held up as illustrating the credulity, dogmatism and charlatanism of medical men, especially when it is done to serve the anti-vaccinationist party, who do not even take up their stand on scientific grounds, but seem with a certain

wrongheadedness to try and bring scientific theories and practices down to the level of the affairs of ordinary life and to degrade the physician to a lower degree of existence than that of a workman. Several London firms are bringing out hypodermic syringes, stated to be available for blood serum injection, but the only one that conforms to my ideas of asepticism and utility is one manufactured by Burroughs, Wellcome & Co., and with the production of which at an economic rate this enterprising and scientific firm have been at great pains to render this syringe useful and reliable in injecting anti-diphtheritic serum. They have been successful, by producing a syringe capable of being rendered quite "aseptic," in boiling, and the platino-iridium needles with which this beautiful instrument is fitted, are beyond all praise. This syringe is of sufficient capacity to hold 20 cubic centimetres, i.e., seven drams and a half of fluid, and could easily be employed to inject ether in cases of chloroform narcosis or in the case of patients almost moribund, when one is called to attend them. My apology for the above remarks is, that although diphtheria is not a common disease in India, still this remedy has caused quite a stir in medical circles, since the public discussion on diphtheria, which took place at the International Hygienic Congress sitting at Buda-Pesth in the course of the current year, when the experiments of BEHRING and KITASATO were discussed "in extenso."

The treatment of tetanus traumatic or idiopathic by means of injections composed of "anti-tetanic serum," tetanus antitoxin will shortly, I hear, engage some attention from the profession generally.

Dr. MUELLER of Yackadanda, of Victoria is, I am happy to hear, again bringing his *strychnine treatment of snake-bite* before the profession all over the world through the pages of the *Indian Medical Record*. It is to be regretted that a few members of the profession should oppose a remedy such as this that promises well without at least giving it an extensive trial. For it must be remembered that many a valuable therapeutic remedy has been discovered by hard-working general practitioners. Dr. MUELLER, however, need not despair of a hearing in this matter. This remedy in the "tablet form and readily soluble in water can safely be injected," in doses of $\frac{1}{16}$ to $\frac{1}{8}$ grain has been incontestably proven, and it may be mentioned that the uses of these small "discs" renders the treatment of snake-bite more certain and safer, doing away with a necessity of weighing or measuring solutions of this powerful alkaloid, the two latter giving rise to such fallacies as poisoning or overdosing. In all cases of snake-bite with "suppression of urine" a tablet containing gr. $\frac{1}{16}$ of pilocarpine nitrate might well be tried in addition to persistence in the administration of strychnine sulphate or nitrate in gradually diminishing doses.

A Committee of the Association of Fellows (R. C. S. England) took place on 31st October 1894 with Mr. T. HOLMES, President in the chair. A meeting being arranged between the sub-committee of Fellows and "the same of Members to settle matters of collegiate interest."

Sir JOSEPH LISTER makes an appeal for funds to erect laboratories in which to manufacture anti-diphtheritic serum. The projected establishment of an "epileptic colony" at Chalfont, near London, has now become a fact. This industrial colony has been founded by the Society for the employment of epileptics. The farm is the gift

of Mr. PARSONS HOWARD, and consists of 135 acres. The foundation stone was laid by him in the presence of Drs. BUZZARD, FRASER, SAVARY, FLETCHER, BEACH, &c., all well known as alienist physicians. Numerous ladies and gentlemen are interested in the charitable work. There are now about 20 colonists. The lady superintendent is Miss DE LAROC, and on the Ladies' Committee devolves the task of furnishing. Dr. BUZZARD made a few remarks on the successful nature of this experiment.

Mr. JUSTICE COLLINS recognises the fact that syphilis may be communicable by the practice of witnesses when in court "kissing the book," as it is called.

In Scotland Sir ARTHUR MITCHELL has retired from the post of Commissioner in Lunacy. He is well known as an archeologist. Dr. FRASER, the Assistant Commissioner, who has held his present post for 18 years, will perhaps succeed him. Sir JAMES RUSSELL, M.D., F.R.C.P. Edin., the first medical man who has held the chair as Lord Provost of Edinburgh, has just terminated his three years of office. Dr. WALTER DICKSON (whose father had been an East India Company's Surgeon) R.N. is the author of many papers on tropical fevers, &c., was a sufferer from glycosuria has just passed away owing to the development of a large carbuncle at the back of his neck. He was late H.M. Inspector of Customs, and had reached his 74th year.

Dr. G. SIMS WOODHEAD, M.D., and G. C. WOODHEAD have been carrying out an extensive enquiry as to the relative value of *water filter* and their efficiency in the prevention of disease. The reports being published in recent numbers of the *British Medical Journal* in a tabular form.

A deputation of the Parliamentary Bills Committee of the British Medical Association has waited upon the Home Secretary (Mr. ASQUITH) pointing out to him the excessive mortality among infants born of *women employed in factories* and certain amendments necessary as to certification of death, with a view to prevention of crime. Sir WALTER FOSTER assured the deputation "that the Government coincided with their reports." He said he did not quite see his way to dealing with "immoral massage establishments," but he quite admitted the accuracy of the deputation's facts as detailed by Dr. ERNEST HART's articles in the current issues of the *B. M. J.*

A girl dying of *plumbism* at the Imperial Enamel Factory, Birmingham, where she was employed as a "brasher" has given rise to considerable excitement, resulting in censure of the foreman of the works, &c.

Dr. GEORGE H. TURNER's report "on the recent out-break of dysentery and diarrhoeal disease at the Suffolk County Lunatic Asylum, Melton" is well put together. He states that the frequent attacks of diarrhoea taking place among the patients at this Asylum terminated in 1893 with the onset of a severe and fatal epidemic, the origin of which he traced to the water supply. Among the organisms found in the contaminated water-supply he notices, besides bacilli, spirilla a large quantity of vegetable matter; and a number of very active amoebae. We regret that he should not have endeavoured to identify these with the amoeba dysenteriae of LEITCH, KILGUTH, LAFLEUR, GONNILLAN, &c., by inoculating cats and dogs with these organisms, so as to produce

typical dysentery would have settled this *quæstio venæ* and thrown some further light upon the relation of these amoebae to the etiology of dysentery and also causal factors of tropical hepatic abscess.

The Home Secretary has given notice that he intends to schedule *brass-casting* and mixing as dangerous occupations. It giving rise to a dangerous complaint formerly styled "brass founder's ague," which is now more definitely known as poisoning by soluble copper salts.

The *British Medical Journal*, beginning with 3rd November 1894, published a somewhat interesting series of letters from divers correspondents entitled "The New Pharmacy" the subject of which is practically the use of drugs in "tabloid" form. This is certainly a *sine qua non* for practitioners in India, and will doubtless eventually meet with their full approval ere long. We will discuss this subject fully in all its bearings in our next epistle, as it certainly merits some notice.

At the West Kent "Medico-Chirurgical Society, Mr. ARBUTHNOT LANE read a paper on the uses of sulphur in surgery and Dr. GEORGE HEASCHELL gave his value in therapeutics of the various iron preparations and salts. He gave his clinical results derived from the administration of various forms of iron to 63 patients at the National Hospital for Diseases of the Heart. The hæmoglobin being estimated before and after treatment by VON FLEISCHER'S hæmometer. He thus proved that the best form to administer iron was BLAUD'S pill "tabloids;" these giving a daily average increase of hæmoglobin to the extent of 1·2 per cent.

Professor CLIFFORD ALBUTT delivered the second of the Armitstead Lectures at Dundee, choosing for his topic "Nerves and Modern Life." He took a most optimistic view of the grand future of the English race. "Mr. T. BRYANT took the chair at the annual prize distribution of the Bristol Medical School, and when he had distributed the various prizes, he gave a pertinent address on "Professional Education," describing the present teaching as grandmotherly, and urged the students not to be mere recipients of knowledge, but all should let individual thought be the groundwork of their medical education; above all, to cultivate the senses; especially let that of sight take the first place. Hands off, said he, until you have thoroughly inspected your patient, and in handling the patient let lightness of touch govern all your actions. You will thereby acquire more accurate knowledge. Dr. M. SKERRITT (the Dean) stated in his report that there were 94 students on the books.

Surgeon-General JOHN FRASER, M.D., C.B., who served for 20 years in the Army Medical Department, we regret to say has passed away, leaving a brilliant record of service as an Army Surgeon. Dr. FRASER was the son of Rev. SIMON FRASER of Stornoway, was born in 1819, was educated at Aberdeen, Glasgow and Edinburgh Universities, M.D. 1840, joined A. M. D. 1841, gazetted full surgeon 1852. In 1858 he became Deputy Inspector-General, served with the Rifle Brigade throughout the Crimean War, during these 6 years, being present and gaining distinction at Alma, Inkerman and Sevastopol (Crimean medal, 3 clasps, Legion of Honor and Turkish medal). He saw much active service during the Indian

Mutiny through Bengal and N.-W. P.; he was at the capture of Lucknow and other engagements, twice mentioned in despatches by Sir HOPKINS GRANT, while serving in Oudh (Indian medal with clasp) and was made C.B. in 1859. For long years after this he served in the A. M. D. He retired in 1879, when he was appointed Honorary Physician to the Queen. In 1892 he was accorded a distinguished service pension. In character this good man was retiring, modest and humane. Since his retirement, he had resided at Edinburgh. On the November 14th, at 21 Chalmers Street, he succumbed to a second attack of cerebral hæmorrhage, and passed from our sight, but not from the hearts of those that knew him. All those whom he met with or associated felt a strong impression as to his indefinable influence upon them for good. He was director of many charities in Edinburgh, where his good offices will be remembered for long years by many of the poor or needy; for he had a helping hand extended to all.

Current Medical Literature.

MEDICINE.

Hysterical form of Raynaud's Disease.

DR. LEVI is of opinion that there is a certain form of RAYNAUD'S disease, which is purely hysterical in origin. It may be caused by, or reappear under, the influence of a strong neurotic element, brought about by the existence of a "subconscious fixed idea." It can be made to disappear, or at least can be considerably ameliorated, under the influence of hypnotism, but leaves an appreciable effect on the vaso-motor system, which can be more easily influenced than before the primary attack. In such cases a history of a previous attack of rheumatic fever is very common, and the parts which were then chiefly attacked are often selected by the condition now under consideration. The onset is sudden, is usually accompanied by urinary symptoms—either auria or polyuria—and gangrene is possible in this condition. Cases of RAYNAUD'S disease, which have been considered of hysterical origin, and which have been treated by hypnotism, are rare; but examples of local congestions in hysterical subjects, or which have been caused by the emotions, are numerous. The above observations are offered by DR. LEVI as a contribution to diseases caused by the emotions. They form an addition to the list, already a long one, of the vaso-motor phenomena associated with hysteria. These symptoms cannot be considered to form a definite disease in themselves, but are a part of a series of phenomena which may take the place of one another, and in the form now described are caused by the same neurosis—hysteria. DR. LEVI accepts the theory of a central origin of hysterical affections, and points out that for their treatment a careful inquiry should be made into the psychological history of the patients, so as to enable the physician to detect any neurotic tendency, and so exclude the possibility of organ disease. He considers that hypnotism is of great value, both as regards the diagnosis and the treatment of such cases.

Chlorosis.

F. W. WARFVINGE accentuates the importance of a clearer comprehension of this disease, as distinguished from the various forms of anemia. He believes in its spontaneous origin, in its almost exclusive occurrence in females, and its appearance at the period of puberty. In fifty cases observed by him in the Sabbatsberg Hospital, some slight and some severe, the quantity of hæmoglobin was, without exception,

much reduced,—from 45 to 85 per cent.,—the average being 62.5 per cent. This diminution is, according to him, the predominant factor in the production of disease. In only four cases was the number of red corpuscles normal (5.1 to 4.7 milligrammes), but in all others it was lowered (lowest, 1.6 milligrammes; average, 8.85 milligrammes), the reduction of the hæmoglobin being, therefore, proportionately much greater than that of the red blood-cells. In twenty cases of anemia of advanced phthisis the number of the red blood-cells amounted, on an average, to 4.89 milligrammes and the hæmoglobin to 80 per cent. Sixteen cases of chronic parenchymatous nephritis showed, on an average, 3.7 milligrammes of red blood-cells and 68 per cent. of hæmoglobin. In pernicious anemia the hæmoglobin maintains a higher, or at least as high, an average as the red blood-cells, which is not the case in chlorosis. As to treatment, administration of iron (Blaud's pills) in large doses is of the utmost importance, while in symptomatic anemias dietetic prescriptions are the chief feature, the iron playing only a subordinate part.—*Hygiea*.

Putrefactive Gases as Predisposing Agents in Typhoid Infection.

DR. ALESSI has made experiments which throw some light upon this subject. Rats, guinea-pigs, and rabbits were confined in boxes with perforated bottoms, and these boxes were then placed over open privies or cesspools, or over receptacles containing the evacuations of the animals. Notwithstanding that they continued to eat well, the animals lost their liveliness, and gradually pined. They were inoculated in this state with a small dose of typhoid bacillus, with the result that they died in twelve to thirty-six hours. The examination showed signs of hæmorrhagic enteritis, swollen Peyer's patches and spleen, and typhoid bacilli in the blood, liver, and spleen. The same dose had no effect upon the majority of the control animals; only a few showed slight symptoms of illness, and one died. These experiments go to show that animals are rendered highly sensitive to the typhoid bacillus by previous inhalation of the gases of putrefaction. ALESSI next investigated the isolated action of the various gases produced in putrefaction, to ascertain if any one were capable of creating the predisposition referred to. The result was in each case negative. The same held good as regards certain mixtures of these substances.—*Centralblatt für Bakteriologie*.

Graves' Disease and Thyroidectomy.

At a recent meeting of the American Neurological Association, DR. F. PETERSON recorded the case of a female patient, aged thirty-four, whom he saw in 1888 on account of certain symptoms which had been coming on during the previous seven years. There were present marked tachycardia (the pulse-rate being 120), proptosis, tremor of the hands, sweating, and flushing. There was enlargement of the thyroid gland, especially on the left side, where the enlargement was so great as to give rise by its size alone to discomfort or even distress. Removal of the more enlarged side of the gland was advised, and a year later this was successfully carried out by DR. HALLEN of Linköping in Sweden, who removed the whole of the left lobe. Improvement began immediately after the operation in 1889 and has gone on steadily, so that now, five years after the operation, there is no proptosis, no tremor or thyroid swelling, and the patient has been able to carry on her work comfortably ever since the operation. The only symptom that remains as a relic of the former trouble is a somewhat rapid pulse. This case certainly suggests that the operation has had an excellent effect upon the condition.

Croup and all Croupous Diseases Curable by Pilocarpin.

SUCH is the title of a paper presented by DR. SZIKLAI at the Eleventh International Medical Congress in Rome. DR. SZIKLAI insists upon a difference between croup and diphtheria. Pilocarpin causes a profuse secretion of physiological mucus between the membrane formed by coagulation of the transudation and the mucous membrane in which it lies, which secretion undermines and thus raises the false membrane. The false membrane being thus loosened, it acts as a foreign body in the larynx, and is coughed up. The further action of pilocarpin should, with the elimination of the formed membrane, the diseased process not come to an end, *is to rob the transudation of its fibrin*; so that a reformation of the membrane under the use of the drug is rendered impossible. DR. SZIKLAI gives the following doses:—

| | | | |
|------------|------------------|-------------------------------------------|--------------------|
| 0-1 years, | dose 1-2 centig. | ($\frac{1}{100}$ to $\frac{1}{100}$ gr.) | pilocarpin pro die |
| 1-3 " | " 2-3 " | ($\frac{1}{100}$ to $\frac{1}{100}$ gr.) | " " |
| 3-6 " | " 4 " | ($\frac{1}{100}$ gr.) | " " |
| 6-10 " | " 5 " | ($\frac{1}{100}$ gr.) | " " |
| 10-15 " | " 6-7 " | ($\frac{1}{100}$ to $\frac{1}{100}$ gr.) | " " |
| Adults, | " 8-10 " | ($\frac{1}{100}$ to $\frac{1}{100}$ gr.) | " " |

DR. S. further advises the use of pilocarpin in croupous diseases of all mucous membranes. It is indifferent whether the drug be taken by the mouth or subcutaneously injected. The earlier pilocarpin is given, the prompter its results.—*Journal of Laryngology.*

Hepatic Colic without Gall-stone.

LEPINE contends that hepatic colic may result from simple spasmodic contraction of the gall-bladder or biliary duct. This opinion is based on both clinical, pathologico-anatomic, and experimental evidence. From the clinical point of view, reference is made to the hepatic colic observed in hysterical individuals as a result of emotion, without discoverable cause in the intestinal evacuations. In some individuals the ingestion of certain articles of food is followed by hepatic colic. A case is cited in which after death no concretions were found in the choledoch duct, although a few small grains were present, together with active contraction of the walls of the duct. In dogs spasmodic contraction of the lower portion of the choledoch duct may be induced artificially. It is maintained that contraction of the biliary canals may be induced reflexly.

—:O:—

SURGERY.

Progressive Myopia and its Treatment.

IN an instructive paper published by DR. KUHN (chef de clinique of DR. DEHENNE of Paris) in the *Medicine Moderne* of Nov. 10th, that authority tells us that he recognises two forms of myopia—stationary myopia, due to lengthening of the axis of the eye, and progressive myopia, which is accompanied by lesions of the membranes, and which is a kind of glaucoma. The first variety is amenable to the use of lenses properly chosen; the second requires special treatment. The most common concomitant symptoms and lesions of progressive myopia are the perception by the sufferer of broken lines, posterior sclero-choroiditis, atrophy of the choroid, floating bodies, softening and detachment of the vitreous, detachment of the retina, and atrophy of the zonule of Zinn, involving subsequent dislocation of the lens. DR. DEHENNE explains these troubles by supposing that there is hypersecretion of the intra-ocular fluids, with increase of globe tension and consequent lengthening of the axis. The sclerotic is distended, and the choroid, being less distensible than it is, torn here and there. This leads to posterior staphyloma, migration of pigment granules, and the development of chorio-retinitis, with deposit of patches on

exudation. It is these patches which produce at the macula the sensation of broken lines, just as the macula lutea complained of by the patients are caused by the presence of the escaped particles of pigment in the vitreous. The retina ends by becoming detached from the choroid, and the other lesions spoken of above follow. The prognosis need to be most unfavorable, blindness too often being the consequence; indeed, the condition above described was always considered incurable. Iridectomy and drainage had been tried and found wanting in the majority of cases. Since 1882 DR. DEHENNE has had recourse to sclerotomy with invariable success. It is stated that every patient was able to use the eyes without fatigue after the operation. Ophthalmoscopic examination of patients operated on years ago has shown that the lesions had become arrested. DR. DEHENNE practises sclerotomy directly floating bodies appear, and immediate operation is indicated when the sensation of broken lines is complained of together with ocular fatigue, or, *a fortiori*, when posterior staphyloma and choroidian atrophy are made out. The operation is safe and painless; in two days the patient can resume his ordinary occupation.

Injury to the Cauda Equina and Lumbar Enlargement.

PROFESSOR SCHULTZE of Bonn relates an interesting case of which a short abstract appears in a recent number of the *Neurologisches Centralblatt*. A young man aged twenty-one years fell a distance of eight metres on his hips, and suffered afterwards from pains in his legs and sacrum and numbness as low as the knees, with incontinence of urine and feces. After nine months he could walk with crutches, his gait, however, being feeble and his knees and feet rotated outwards. There was some prominence of the second lumbar vertebra, and there was a great amount of atrophy below the knees, the left gastrocnemius, soleus, and tibialis anticus and posticus muscles being almost completely paralysed. On the right side also below the knees the muscles were almost completely disabled. The gluteal regions also on each side were much affected, and so was the region of the sciatic and of the superior and inferior gluteal nerves, while the muscles supplied by the cruralis and obturator nerves remained free. There were also fibrillary twitchings in both glutei. In both peroneal regions, except in the peroneus longus and extensor communis digitorum, there was complete reaction of degeneration, and in the calf muscles partial; while in the glutei there was loss of the direct electrical excitability. The knee-jerk on each side was abolished, and the cremaster reflex was weak. There was weakness of the sphincter ani and of the detrusor vesicæ, but no priapism. Sensibility was much impaired on both sides below the knee and on the back of the thigh, and there was anaesthesia of the scrotum and perineum; while there was hyperæsthetic zone on both sides in the region of POUPART'S ligament. It is not easy, PROFESSOR SCHULTZE says, in this case to decide whether the cord itself, or only the cauda equina, or both, were affected.

Surgical Brevities.

Carbolic Acid applied in official strength in surgery.

1. No systemic absorption attends its use, and hence no danger, no shock.
2. It is a local anæsthetic. Hence there is not as much pain after the operation.
3. It is in a measure a hæmostatic, acting especially upon the capillary vessels.—GARDNER.

Ingrowing Toe-nail.—Remove all of the redundant, hypertrophied, or granular tissues of the skin, and leave the nail alone.—NUDING.

Repeated small rectal injections, it is said, will relieve the intense thirst following abdominal operations.

Alcohol will be used less and less in surgery, because scientific investigation has shown the causes of many of the evils it was imagined to counteract, and because, thanks to Sir JOSEPH LISTER, these causes have been got rid of.—HORSLEY.

Granular Lids.—Curetting and brushing with corrosive sublimate is successful in mild, but not suited to bad cases.—TROUSSEAU.

Management of the Intestines after Abdominal Section.—When the general condition of the patient is fairly good and the abdomen is not distending, and when there is not much colic, let things take their natural course. This advice holds for the great majority of cases.

Stricture.—External urethrotomy with SYME's staff and TEELE's probe gorget, is preferable for all strictures of the deep urethra, where gradual dilatation is impossible.—ROSENSTEIN.

The Treatment of Fractures in Children.

LELOIS concludes a study of fractures in children and their treatment as follows: Fractures in young persons differ from those in adults by the frequency of their seat at the junction of the epiphysis with the shaft, the preservation of the periosteum and the rapidity of union. This last fact is due to the greater activity of the elements that participate in the reparation of bony tissue. Frequently an excess of this process gives rise to the formation of an undue amount of callus. Such a hyperplasia in the case of fractures about the joints may result in interference with the restoration of normal mobility. Protracted immobilisation must be carefully avoided in the treatment of fractures about joints, and should give way to massage and early passive movement. The treatment of fractures in children by these methods is in most cases attended with excellent results, both as to the speediness of recovery and the restoration of function.

The Therapeutic Value of Ice in Ophthalmic Surgery.

MCGILLIVRAY commends the topical employment of cold in ophthalmic surgery. In case of recent injury to the eyeball the eye is bathed with a sublimate solution (1:5,000), the patient is put to bed and instructed not to open his eyelids, and ice-compresses are applied immediately and continuously. If, after a day or two, no inflammatory reaction has set in, the compresses are withheld. In cases attended with inflammation, the application is continued till the process has subsided. Each compress is removed as soon as it begins to lose its cold feeling, and a fresh one is applied.

Ashes in the Treatment of Wounds.

DR. PASHKOFF, in *Novosti Terapii*, emphatically recommends dressing recent wounds of any kind with a thin layer of ashes prepared *ex tempore* by incinerating some cotton, stuff, or linen. He says dirty-looking wounds should be previously washed out with a boracic lotion. The ashes, with blood, form a protecting scurf under which the lesion heals very rapidly. Of twenty-eight cases of cuts, crushes, stabs, etc., treated after this method, twenty-six quickly healed without any trace of suppuration.

Circumcision for Incontinence of Urine.

A BOY ten years of age had a precipitate way of passing his urine; had a great deal of trouble at school on that account, as he had to run out all at once. I found his trouble was due to a tight prepuce, and he was at once relieved by circumcision.—DR. C. W. SHAW, in *Pittsburgh Med. Review*.

OBSTETRICS AND GYNECOLOGY.

Speedy Method of Dilating a Rigid Os.

DR. FARRAR (Gainsborough) relates two cases of rigid os, in one of which, after endeavouring vainly to relax the cervix by the aid of chloral, bromide of potassium, and morphia, followed by most persevering attempts at digital and mechanical dilation, with and without chloroform, he applied a 10 per cent. solution of cocaine preparatory to incising the edge of the os. After five minutes, on introducing the finger as a guide to the scissors, the os was found widely dilated. In the second case, which, like the first, was that of a primipara, forty-eight years of age, where no dilatation occurred, although the same means as were tried in the first case were used, he waited three days, and then applied the cocaine. In four minutes the os was found to have yielded. He considered the dilatation to be due to the cocaine in both cases.—*Lancet*.

Old Primiparae.

BIDDER has published a monograph on this subject. He finds that primiparae over 40 are common in Dorpat, and from his own observations he notes no special anomalies in pregnancy. It seems, however, that kidney complications and eclampsia are relatively frequent. Abnormal presentations are not more common than in younger mothers. The duration of labor is distinctly longer, but only in the first stage. Operative interference, especially forceps, is frequently needed. Ruptured perineum is not more frequent than in primiparae; the same applies to complications in childbirth. Severe puerperal diseases and mortality from the same are not more common, nor is the mortality amongst the children of old primiparae specially high. In fact, the old theory that old primiparae run great risk is a mere piece of *a priori* reasoning.—*Brit. Med. Jour.*

Maternal Impressions.

DR. HUBERT WORK has a paper on this interesting—if somewhat contentious—subject. He gives the result of his inquiries from several men who have had abundant opportunities for forming opinions or receiving impressions in reference to the matter, and the balance of their evidence at least leans to the opinion that maternal impressions certainly do influence the foetus in utero. He also enumerates several instances which have either come within his own experience or which have been related to him by the practitioner in whose experience they did occur, and it must be confessed that there are some very striking coincidences. He then states his conclusions in the form of the following propositions: (1) that both physical and mental defects follow maternal impressions with such frequency as to establish the relationship of cause and effect; (2) that these conditions are the result of changes in the blood; (3) that the probability of defects in the foetus from mental causes is dependent upon the mental habit, or characteristics, or susceptibility of the mother; (4) that maternal anticipation of a defect in the child has, in itself, no influence in the absence of a strong impression; (5) that the impression need not be lasting to cause defects; (6) that personal maternal injury is no more likely to mark the child than the sight of it in another; and (7) that the defect is not necessarily similar in location or appearance to the object creating the impressions, but is likely to be. The apparent constancy of likeness is due to the reporting of such cases only. Among these propositions there are no doubt several which would not receive universal assent.—*Philadelphia Medical News*.

The Coup de Grace in Labor.

A CORRESPONDENT sends the following, for the truth of which he vouches:—A young doctor, who began his practice in Texas, west of Houston, was called to a confinement case

in which he, being green and nervous, naturally had some trouble, the patient seeming unable to make the supreme effort for final expulsion. The only other occupant of the wretched quarters was an old crone in a sun-bonnet who was silently but steadily rocking herself near the foot of the bed. Finally the old woman croaked out, 'Doc, I wouldn't bother any longer with that woman, I believe I'd quill her and have done with it.' The medical man not knowing what 'quilling' meant answered that he did not quite see the necessity for that yet. The old woman repeated this suggestion several times until finally the nervous, exasperated man turned angrily on her and said, 'Madam, I'll be it—if I will tie it. If you want to quill her you can do so, but I won't.' The crone took from the wall a turkey-wing and drawing a feather from it proceeded to fashion something like a long quill tooth-pick and filling this with snuff from her own private stock leaned over the patient, and as the next pain came blew the snuff into the woman's nostrils. Quick as a flash the woman responded with a giant sneeze and the child was born with the sneeze. 'Thar,' said the old woman, radiantly, 'I knowed mighty well that thar bust would make her break her holt.' And it did, to the great instruction of the attending physician."—*N. Y. Med. Rec.*

Fatal Metrorrhagia in Purpura.

RESNIKOFF observed this condition in a girl, aged 15, with no hereditary history. Diffuse ecchymoses and petechiae appeared for eighteen months; then bad attacks of epistaxis took place and continued for several months till the period was first established. Clots were discharged for a week. For three months the epistaxis ceased, and at the end of that time recurred. The second period was seen nine months after the first, and proved fatal. For the first week the shew was slight; during the second clots were passed and symptoms of acute anemia set in. Notwithstanding the application of hæmostaties, the patient died of the hemorrhage on the nineteenth day.—*Gazette Hebdom. Med.*

PHYSIOLOGY, PATHOLOGY AND BACTERIOLOGY.

The Vagus and the Secretion of Acid by the Stomach.

LEUBUSCHER and SCHAFER, who are duly corroborated by PAWLOW, SCHUMOVA, and KREHL, have proved by experiments that section of both vagi below the recurrent laryngeal nerves induces waste, loss of appetite, and ultimate death. In animals in which such section was performed no free hydrochloric acid was found in the stomach, and the gastric juice exerted little digestive action.—*Centralblatt Medicin.*

The Function of the Supra-renal Gland.

As the result of a further study AULD concludes that the functions of the supra-renal gland are the destruction of certain effete products of metabolism which are of the nature of ptomaines, and the elaboration of a secretion which is absolutely essential to the blood (hemopoietic). The destruction of the gland is followed by an auto-intoxication and a profound alteration in the chemistry of the blood, which entails, amongst other things, degenerative or nutritional changes in the nervous and digestive systems, and derangement of the color-regulating metabolism.—*British Medical Journal.*

Pathological Changes in Mucous Membranes.

Mr. D'ARCY POWERS exhibited to the British Medical Association a series of preparations of the conjunctival and vaginal mucous membranes taken from rabbits and guinea pigs which had been subjected to mechanical and chemical

irritation. Many of the epithelial cells presented appearances which were identical with those described as being parasitic when they were met with in cancer. The changes in the epithelium were summarised as a general vacuolation of cells; various forms of intra-cellular oedema; epithelial "pearls," collections of leucocytes, and the spaces left after these leucocytes had migrated. The series of preparations shewn on the present occasion indicated that many squamous epithelial cells had the power of phagocytosis, for in no other way could the remarkable intra-cellular appearances be explained; cells were shewn containing a leucocyte, and others containing a microcyte. Partial necrosis of the cell also took place as a result of irritation, and there was an invasion of large eosinophile cells into the conjunctival epithelium.

Cholera and Flies.

COMMENTING on the recent outbreak of cholera in the Gaya Jail, Surgeon-Major R. MACRAE noticed the presence of swarms of flies in the jail and their easy access to either excreta or food, and contends that even though the comma bacillus may not be the cause of cholera, still it is intimately associated with that disease and the agency which can disseminate that micro-organism is also competent to distribute any other material which may be the cause. He points out that though no direct proof is tendered of the actual transmission of cholera from excreta to food and water is universally made the scape goat, still the probabilities of such transmission are greatly assured by PROFESSOR HAFPEKE's discovery of comma bacilli in sterilised milk exposed in new vessels to which flies were permitted free access, and it has been found that these flies had equally free access to ill-managed cholera dejecta.

PUBLIC AND DOMESTIC HYGIENE AND JURISPRUDENCE.

Eucalyptus useless against Malaria.

UNDER the heading "The Passing of the Eucalyptus," the *Journal of the American Medical Association* states that the Consuls of the United States in Europe report unfavorably on the supposed virtues of the eucalyptus. The Trappist monks of Tre Fontane, three miles from Rome, have planted since 1873 no fewer than 50,000 trees on a few acres. In 1880 the Government established an agricultural colony of penitentiary convicts in quarters supposed to have been already improved by the eucalyptus. The convicts were surrounded by hygienic conditions far superior to those of the laborers of the Campagna, yet nearly all became stricken with malarial fever within a year after their arrival. In 1883 all the inhabitants of Tre Fontane were attacked. The guards at the colony had all to be changed. The efficacy of the eucalyptus for the improvement of the air is no greater than that of the elm, plane, and mulberry. If it recommends itself by rapidity of growth, the trees just mentioned recommend themselves by being hardier and more easily grown. PROFESSOR LIVERSIDGE, of the University of Sydney, stated long ago that in the southern hemisphere, where the eucalypti thrive best, there are forests of these trees where malaria is specially noxious. The tree itself is no ornament, the continually spontaneous peeling off of the bark producing an unsightly effect.

Disease and Intemperance.

WE have already on several occasions called attention to the unwarrantable construction which has been placed by certain persons—perhaps not altogether disinterested on the Report of the Collective Investigation Committee with regard to the connection of disease with habits of intemperance. In spite of our frequent warnings and explanations on the subject, the misleading assertions continue to be made, and in

consequence the following memorandum, signed by DR. NORMAN KERR, Chairman of the Inebriates Legislation Committee of the British Medical Association, has recently been drawn up. Copies of the memorandum can, we understand, be obtained on application from DR. NORMAN KERR, or from the General Secretary of the British Medical Association. The following are the terms of the memorandum :—

"The attempt to construe the statistics published by the Collective Investigation Committee of the British Medical Association as proving that intemperate drinkers live longer than teetotallers is quite unwarranted, and is in direct opposition to the conclusions of the reporters themselves as expressed in their report. Teetotalism, as they suggest, has only of late years been largely practised in Britain, but drinking to excess has had great antiquity; therefore, the average age of living abstainers must be less than the average age of the rest of the community. So that the average age at death of abstainers being 53 years as against 58 in the cases of drunkards at death proves nothing against abstinence. The accuracy of this explanation is proved by other tables given in the report. When death under 30 years were excluded, the average age of the abstainers was about four years more than that of the decidedly intemperate. When deaths under 40 were excluded the average age of the teetotaler at death was more than five years greater than that of the intemperate. To guard against misrepresentation or misunderstanding, the Committee expressly stated that the returns reported on afford *no means* of coming to any conclusion as to the relative duration of life of abstainers and 'habitually temperate drinkers;' that habitual indulgence in alcoholic liquors *beyond the most moderate amounts* has a distinct tendency to *shorten life*, the average shortening being roughly proportionate to the degree of indulgence; and that *total abstinence* and habitual temperance *augment* considerably the change of death from *old age and natural decay*.

The Curse of Kissing.

A WESTERN contemporary waxes warm on the subject of kissing being a sanitary sin, even though when properly applied, both as to time and place, asculation may be mutually agreeable and fairly healthy. He deprecates the practice of beslobbering helpless infants and snatching kisses from young girls and unprotected females whenever opportunity offered. He points out that syphilitics, tobacco chewers, tuberculous subjects and persons with very bad teeth are the greatest kissers of infantile and youthful humanity, and consequently the greatest transmitter of their respective maladies. He cautions as to the heed of implanting terrible diseases by the time honored yet highly insanitary "sick-bed kissing" and applying the warm lips to the clay cold forehead or lips of the dead, and winds up an interesting discourse by telling every one in the world that we should carefully instruct our little ones in 'mouth hygiene' and never neglect an opportunity to strike at the mouth which bears a mucous patch or where lurks the poison of phthisis or to defend the defenceless babe from the onslaughts of the male and female kissers.

Exhumation after fourteen years' Burial.

ON 13th November, by licence of the Home Secretary, I inspected the contents of a coffin which had been buried in April 1880. The reasons for the licence are not material. The man was 23 years of age at the time of his decease; the cause of death was "peritonitis," and he was buried in an iron coffin, and in a stratum of clay. On lowering the lid of the coffin it was found to be full of water. It was placed upon a bier, and a hole driven through it to drain it. The name-plate on the lid was still quite legible. On removing the lid

a powerful nauseous odour came from the remains. The linen was discolored, but in a fair state of preservation. The features were obliterated; the hair and teeth still recognizable. The skin and the whole of the soft tissues were converted into a soft, greasy, yellow-white, soapy or putty-like material, crumbling upon the slightest touch, and exhaling a loathsome odour. The skull was dislocated from the spinal column, the vertebrae of which were scattered about in various parts of the coffin; the lower jaw was dislocated from the skull; the other bones were dark colored, perfectly smooth, and without a vestige of periosteum, appearing as if macerated, and were easily removed from one another and from the slimy mass of adipocere surrounding them. The lid had been soldered on to the coffin at the time of interment, and the period of entrance of the water is conjectural. The result, apparently, was that circumstances were here combined to retard decomposition to the ultimate extent possible, so that after fourteen and a-half years' burial the corpse was, even to an "acclimatised" dissecting-room curator, abnormally repulsive. —J. R. M. BRENNAN, M.B.C.S., L.S.A.

—:O:—

THERAPEUTICS AND PHARMACOLOGY.

Physiological action of Alcohol.

DR. DAVID CERNA thinks that small doses of alcohol excite the peripheral motor and sensory nerves, stimulates the cerebral functions, accelerates the cardiac beats, raises arterial pressure and the bodily temperature, and have little or no effect on the respiratory function; but in large doses it not only acts as a depressant in all the foregoing and causes lack of co-ordination, but also by first increasing and then diminishing reflex actions enhances coagulation of the blood and finally kills by failure of respiration. By diminishing the absorption of fats and the excretion of tissue waste, increasing the activity of the kidneys, eliminating carbonic acid, assisting the absorption of oxygen, conserving tissues and generations, vital force, alcohol may be looked upon as a food that aids digestion, and is mainly burnt up in the system when taken in moderate amounts. In longer amounts it has a decided antipyretic action; but its excessive or long continued use causes spiral degeneration of the axis cylinder of nerve-fibres, produces cirrhotic changes and leads to epilepsy, insanity, paralysis and other maladies, while in toxic doses it produces hyperemia of both brain and spinal cord and destroying the oxidizing power of the blood, separates the hæmoglobin from the corpuscles.

Diphtheria Treatment.

AT Halm's clinic, Berlin: Application of ice collar, hourly gargling or spraying with 4 per cent. solution of chlorate of potassium, or 1 to 4,000 solution potassium permanganate in cases where fetor is present. In usual diphtheria, syringing of nasal cavities with 2 per cent. boric acid or 1 to 4,000 permanganate solution, plugging nostrils if epistaxis occur. Steam in cases of laryngeal obstruction. If urgent dyspnoea, low tracheotomy, removing cannula on fifth or sixth day.—*Dent. Med. Week.*

Treatment of Purulent Ophthalmia in Infants.

M. KALT, of Paris, treats the above serious affection by abundant irrigation by means of a 1 in 5,000 solution of potassium permanganate. The apparatus devised by him for this purpose consists of a small funnel, the nozzle of which is introduced between the eyelids, while the other extremity is connected by means of a tube with a reservoir placed at a height of thirty centimetres above the eye. Each irrigation

is effected every morning and evening with two litres of the solution at a temperature of from 80° to 85° C. Where corneal ulceration exists four daily irrigations must be practiced for the first three or four days, after which they may be made less frequently. The douching must be continued until all secretion has ceased.—*Med. News.*

Rationale of the Cold-bath Treatment of Typhoid Fever.

It is already known that the employment in typhoid fever of what is denominated in this country and in Germany as BRAND's method (it should be more justly called CURRIE's method) has the effect of increasing the flow of urine. But what was not hitherto known is the increase of urine toxicity that is brought about by this mode of treatment. In typhoid fever the normal toxicity is diminished by two-thirds. The cold-bath treatment restores from the first few hours the toxicity to the normal and perseverance in the method determines its further increase (sometimes to double the normal). It is evident that by this means the system is cleared of a large quantity of toxins, and it would seem that it is in this direction that he must look for the beneficial effects of the cold bath in apparently desperate cases. This observation is due to a French army surgeon, M. AUBERT.—*Lancet.*

Treatment of Chronic Articular Rheumatism.

LETULIE recommends rest in bed, the repeated application of the actual cautery to the affected articulations, passive movements of the joints, sulphurous baths, alternative with warm douches of simple or sulphuretted water, in conjunction with the internal administration of potassium iodid in doses of from 7½ to 30 grains in the twenty-four hours.—*La Presse Medicale.*

Chloroform Treatment of Phthisis.

In the *Journal de Medicin de Paris*, M. POTTER urges that by the inhalation of chloroform the bacillus of tuberculosis is destroyed *in situ*. It is not necessary to produce anaesthesia, but short of this inhalations should be employed at brief intervals daily for a considerable period.

A Good Pepsin Mixture for Dyspepsia.

| | | | |
|------------------------|-----|-----|--------|
| Pepsin, B. P. | ... | ... | 3j. |
| Acid. hydrochlor. dil. | ... | ... | 3ij. |
| Glycerini | ... | ... | 3vj. |
| Tr. carb. co. | ... | ... | 3iv. |
| Inf. gent. ac. | ... | ... | 3viij. |

Put the pepsin in a mortar, add the acid and triturate well, then add the glycerine and other ingredients in their order.—*C. & D.*

Zinc and Belladonna in Whooping-Cough.

| | | | |
|---------------------|-----|-----|------------|
| R. Zinc Sulphatis | ... | ... | 4 grains. |
| Tincture Belladonnæ | ... | ... | 48 minims. |
| Aque Anisi, ad. | ... | ... | 2 ounces. |

M. Sig.: Twenty drops every third hour for a child one year old, thirty for a child three years old, sixty for a child five years old, and so on.

Pruritus Ani.

A FAVOURITE prescription of DR. HAYES AGNEW, recommended as almost a specific in pruritus ani (says the *Therapeutic Gazette*) is:—

| | |
|-----------------------------|--|
| R. Sulphate of zinc. | |
| Alum. of each, equal parts. | |

Pignola Macaroni.

TAKE one cup of macaroni, add one pint of milk, two tablespoonfuls of flour, salt to taste, and six tablespoonfuls of pignola roasted and chopped fine. Put into a shallow pudding dish, and bake in a moderate oven until nicely browned.

Apples Stewed in Tomato.

TAKE stewed and strained tomato, and cook slightly tart apples in this as in water. Serve without the addition of sugar. The combination of the apple and tomato makes the sauce taste sweet. Salt may be added if desired.

Correspondence.

DR. BAHADHURJI ON MEDICAL EDUCATION AND THE MEDICAL SERVICES OF INDIA.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—The following is the speech I made at the recent meeting of the national Congress in moving Resolution XIII which is as follows:—

"This Congress is of opinion that the present constitution of the higher medical service is anomalous, and indefensible in principle, injurious in working, and necessarily costly. The time has arrived when, in the interests of the public, the medical education and the advancement of the medical service and scientific work in the country, and also in the cause of economic administration, the civil medical service of India be reconstructed on the basis of such service in other civilised countries, wholly detached from and independent of military service. That the very unsatisfactory position and prospects of the members of the subordinate civil medical service (Assistant Surgeons and Civil Hospital Assistants) compared with members of similar standing in other departments of the public services, require thorough investigation and redress, and the Congress prays the Government to grant an open inquiry by a mixed commission of official and non-official members. While viewing with satisfaction the desire of the Imperial Government to reorganise the Chemical Analyser's Department, with a view to its administration as an independent scientific department, the Congress earnestly hope that Government will not fail to recognise the responsible and meritorious work of the assistants and place them on the footing of specialists."

The subject of the resolution I have just read to you has engaged such a considerable share of public attention since it was first spoken to from the Congress platform last year, that I need hardly enter into details again. The question of Simultaneous Examinations is, no doubt, of great importance to the public, but you will agree with me that the subject of the medical service of the country is of equal, if not greater, public importance, and that it is a matter of surprise and regret that it should have so long remained unnoticed by our popular leaders. They would seem not to have noticed that, in the very matter of Simultaneous Examinations, the Covenanted Medical Service of India most directly demonstrates that the opponents of Simultaneous Examinations have rather overstated their case and drawn on their imagination as regards their *sine qua non* of a long residence in England for the acquiring of that mental, moral and magnetic equipment which alone can impart the necessary administrative ability, courage, and social adaptability to Indian youths as members of the I. C. S. For, indeed, many an Indian member of the Covenanted I. M. S. had only to voyage to England to pass the Burlington House Examination to obtain his commission; and this accomplished (in a few weeks after arrival in England), he had only to put in his regulation six months at Netley before he returned to India as a member of the I. M. S. What, then, have the opponents of Simultaneous Examinations to say to the fact of not only Indian members of the Covenanted I. M. S. acquiring administrative ability, courage and social adaptability—qualities required in no smaller degree in the military than in the civil department—but also imbibing a martial spirit, by the mere effort of a trip across the sea to obtain a commission in her Majesty's army? To examine briefly the subject of the resolution, let us study the different parts separately. I

shall deal mainly with the first two sections, leaving the rest to my friends who will follow me. The first part says that the constitution of the higher Civil Medical Service is anomalous, indefensible in principle, injurious in its working, and very costly, and requires to be revised and remodelled on the basis of what obtains in other civilised countries. To realise the absurdity and the mischief of the present constitution of our Higher Civil Medical Service, let us contrast it with what it is all the world over. The Civil Medical Service of any country is concerned with the several departments of education, of sanitation, of special scientific and expert work, as of chemical analysis and of civil medical relief. The practice outside India is to recruit the service from the open profession of medicine and science, the necessary qualifications being special training and ability and no mere ordinary practising license or degree, and to find men for posts and not posts for men. But in India it is far otherwise. The selection is restricted to a small class of men who form the stock-in-trade, so to say, of a military dépôt, called the Indian Medical Service. The competition for this service is open to any who possesses a British qualification in medicine, surgery and midwifery, and many of our graduates and even plucked students who could afford a trip to England scored such easy victories in the competition not many years ago that their overwhelming numbers raised an alarm and led to the closing of the service against them for the time being. It was thrown open again, no doubt, but as is well known some agency or mystic force has since prevented the Indian candidates regaining their old position in the pass list. This covenanted military service requires for its own military purposes—the purposes for which its enlistment is intended—some 170 men; but, like other dépôts which always have a large stock of articles lying idle, this service dépôt has in its fold more than twice that number of men for whom the Military Department has neither room nor work, and it is for these supernumerary military men that work is found in the Civil Department, as posts become available. It is these extra or floating military men that are trotted out in plain clothes as professors or political agents, guardians of jail birds or Civil Surgeons, Sanitary Commissioners or Chemical Analysts, etc., etc., under orders from the Civil Military Surgeon-General, i. e., the chief *medecin militaire* in plain clothes. Scientific and expert advisers to all other civilised Governments are individuals who have worked at special and scientific subjects and possess special qualifications. But in India it is a single individual who advises Government on all matters connected with the science of medicine. He is the Civil Military Surgeon-General, i. e., the Military Surgeon-General in plain clothes, distinguished from his brother officer in uniform. He rises to that position not by virtue of any scientific work or merit, but by a special process of development through the grades of Captaincy, Majorship, Major-Generalship, to which last he must gravitate by the mere weight of years. And the mere fact of his donning the hat of the Surgeon-General is taken by the Indian Government to infuse into his head expert knowledge not in one but in all the different departments of science and medicine? Again, the genesis

of a medical professor in India is equally peculiar. All the civilised world over it is by a special training in a special subject after graduation that one becomes a professor. But in India the course of training requires at the outset two years' shooting and messing with a regiment, followed by the experience of a general practitioner, as a Civil Surgeon, or as a guardian of jail birds, or of some such other work. It is after this special process of development or rather degeneration that a *medecin militaire* gets himself electroplated as a professor, should he happen to possess the special connections wherewith to excite the electric fluid in the Surgeon-General's Office. But this is a wonderful fluid; it has the power to make a Professor of Pathology for instance, disappear from the chair of Pathology only to reappear as a Professor of Midwifery! That this is all anomalous and indefensible in principle, and that neither the official medical professor nor the Government medical expert is a genuine article needs no argument to establish. That such a constitution of a Civil Medical Service must be very injurious in its working will be really accepted, and can be easily demonstrated by a few actual examples within one's personal knowledge. Examples are but illustrations of the evils of a system of which the special cases are themselves the victims, and it would be only narrow-mindedness to construe the citation into personal attacks. Under this absurd system, a Professor who has never had any training in Biology—has not even looked into the inside of a frog—becomes gifted with the audacity, not to say imposing impudence to pretend to examine our Arts and Science Graduates in Comparative Anatomy. Under this absurd and mischievous system, the Professor of Zoology has to be a born Ophthalmologist and *vice versa*, and what does his teaching in Biology consist of? Some two dozen readings from text-books from a pulpit decorated with bottled pickles of zoological specimens; the readings over, the class repairs to a museum where a single personally conducted tour by some obliging Curator or Secretary begins and completes the course of practical zoology! Is this not a fraud both on the University and on the public? Under this unnatural system, a Chemical Examiner, who has not a day's experience of his work to boast of, and whilst he is yet learning his work from his assistant, considers it all a very natural thing to report on the work of his assistant, from the superior place into which he finds himself pitchforked. And again, the teaching of Physiology, for instance, may continue to be of the most primitive kind, till an outsider exposes it, works violent changes in the College, and causes the teaching of this very important subject to be entrusted to capable and proper hands. Under this system again, Government by their attempting to extort all possible knowledge from a medical hand which they, as a matter of course, cover with the Surgeon-General's topee when the individual arrives at the age prescribed for such investiture make themselves the laughing stock of the thinking world at the instance of some novel ideas extracted from their Surgeon-General. Not so long ago a Surgeon-General deliberately declared that experimental physiology had nothing to do with vivisection. It does not require much technical knowledge

to understand that the very contrary is the case, for physiology deals with the phenomena of life, and naturally therefore, experimental physiology deals with experiments on living beings! Not so long ago our Government medical advisers did not know the ordinary requirements of scientific research. Three laboratories in the Bombay Presidency have been rendered useless for the purposes for which they were built. One has been turned into a carcass incinerator, another into a godown, and the third one LORO HANAN, the Governor of Bombay, assured us the other day would be put to some useful purposes. Whilst giving this assurance he could not help expressing his surprise that there should be any comment on such waste of public money; for after all the expenditure on these buildings was not a matter of lakhs but only thousands! The *Times of India* remarked the other day that a potter of ice or a pice worth of kerosine oil would give a bacteriologist any desired temperature for his cultivation purposes. This knowledge was unfortunately not in the possession of the highly paid scientific advisers of Government, who were compelled to vote further sums of money for the removal of their scientific and their baggage to some shady regions! But one need not multiply these instances. The monopoly of the I. M. S. not only recoils thus on the heads of the monopolists themselves, but, what is more important from the point of view of the interests of the country itself, it prevents all growth of talent in the country, and degrades the profession of India, as we shall see presently. It has been urged that the appointments must be so reserved for the Imperial purposes of a *military reserve*. To begin with a reserve of nearly 400 men for an effective service of less than half that number is an absurdity in which the Military Department and its apologists alone can revel, but the reserve argument accuses the Government of hypocrisy and dishonesty. The Government have publicly declared that the medical schools were founded for the cultivation of the medical science of the West, for the benefit and happiness of the Indian people, and "not for any Governmental or executive wants," and that they fostered the growth of science and higher education for their own sake. If these then be no longer their intentions, or rather the intentions of our latter day Government, let them say so honestly, and not keep posing as honest patrons of science and education. The conditions under which the growth of science and medical education has suffered so long, carry their own condemnation, and it was time the Indian people, and not only the profession, rose to a man to appeal to the authorities to emancipate medical education and science from the thralldom of an aggressive Military Department, which has no moral or legal right to the monopoly it has built up for itself. The I. M. S. covenant is a purely military covenant, and has no reference whatever to any right, much less an exclusive right to civil appointments. It is only by a thorough emancipation of medical education and science, by throwing open their fields of work to the best talent available in Europe or in India, that India can hope to advance to a forward place in the march of civilisation in the matter of scientific assimilation and growth. Scientific and Medical Congresses in a land where science and the profession of medicine are allowed no fair play, and where there is no such thing as a scientific profession, are but

false emblems of scientific progress. I was asked to join the Calcutta Medical Congress. I should have been delighted to take part in any proper Medical Congress. But I did not join this Calcutta Congress for the simple reason that it is no genuine Congress of a liberal homogeneous profession. Compared with a genuine Congress, it had the elements of sham and hypocrisy in its very constitution. For, look the facts straight in the face. Here is a group of men—the monopolists—asking their bondsmen to rub shoulders with them just for the purposes of a good gathering. Men who have been looked upon as an inferior lot, incapable to rise to the position of their teachers in their own *alma mater*, unfit to take part in the work of scientific medicine, are now suddenly considered fit to discuss scientific work with "masters and superior persons"! A mere Congress gathering gives no unity to the profession in India, and removes not the unjustifiable limitations placed on its Indian members. The question of economy having been fully discussed on previous occasions, need not be again taken up now. Only recently there was some further military plunder, and in the matter of some dozen appointments in the department of jail administration increasing the military expenditure by thousands. It was time this whole question was gone into by an open public inquiry.

To turn to the second part of the resolution, viz., the subject of the Subordinate Medical Service. It has three branches. First, the Assistant Surgeons. These our graduates in medicine, who have passed both educational and professional tests higher than those required for the I.M.S. They begin as Assistant Surgeons on Rs. 100 a month and rise to—well—to old Assistant Surgeons on Rs. 200 a month, fit to retire on the grand pension of Rs. 100, whilst members of the Military Service, who sponge on the Civil Department, rise from Rs. 500 to Rs. 2,500! The Assistant Surgeons do, and have done, all along the work of the Civil Military Surgeons, but without their pay or their position! They have done even distinguished field service as volunteers in the Afghan and other campaigns. The highest career is open to members of every other faculty of our Universities, but it is altogether closed to members of the medical faculty. It is surprisingly strange that members of sister faculties did not perceive so long the unjust treatment accorded to their fellow graduates. A middle grade service, the Uncovenanted Medical Service, on the lines of the uncovenanted counter-part of the I. C. S., was specially created more than 25 years ago for the employment of Indian graduates, but the Military Surgeon-General has contrived to make it a complete dead letter by absorbing every possible appointment above the lowest grade into his military schedule. If, indeed, in twenty years the medical school of Bombay, for instance, has failed to turn out a fit enough graduate for the Uncovenanted Medical Service, it was high time the College constitution was overhauled. The Assistant Surgeons have often complained. Instead of redress they have received nothing but threats from domineering Military Surgeons-General, whose department contrived to keep out all evidence before the Public Service Commission in the matter of the gross wrongs inflicted on their victims of the subordinate service. It was time the

public moved in the matter and demanded an open public inquiry. Of the other two enlistments for the subordinate service one is for purely military purposes and is open to Christians only. But see what difference the element of religion makes in the treatment accorded to the two classes. John the Christian and Pandu the non-Christian both seek admission to their respective services. John the Christian may not know more than the High School 4th standard reading, writing, and sums, but Pandu, the non-Christian, must pass a much higher test. They both go through the same professional course and examination. If anything, Pandu has to undergo a severer examination. John the Christian begins as a Military Apothecary and works under regimental Surgeons. His salary ranges from Rs. 50 to Rs. 450. He may, however, be promoted to the uncovenanted grade and given Rs. 750 by being found a post in the Civil Department. His new designation is Assistant Surgeon, I. M. S., and he rises from the grade of a Lieutenant to that of a Major. But Pandu the non-Christian begins as a Hospital Assistant and dies a Hospital Assistant. His work is as vast as it is responsible. He practises medicine, surgery and midwifery. He it really is who dispels the ignorance and prejudice of the masses in regard to the western system of medicine. He treats a thousand times more cases in a month than the highest officer of a hospital does in a year. On his judgment, intelligence and integrity depend the life of his fellow citizens in the mofussil, questions of life and death turning upon the nature of his evidence in medico-legal cases. But alas! the respectability and responsibility of this most important servant of the State are in an inverse ratio, and that too in very abnormal proportions. One feels almost ashamed to say that the non-Christian Pandu, who does such responsible and excellent work for his Government, is paid no higher salary than is paid to a senior puttawalla in the hospital, or a cook, or a coachman. The scale of his pay is Rs. 16 to Rs. 80 odd. For this great difference in treatment accorded to the Christian Apothecary on the one hand and the graduate Assistant Surgeon, than that the specially favored class of military apothecaries belong to the Christian race? Now that it has been familiarised with these manifest wrongs which scandalise the fair fame of British justice and fair play is it its bounden duty to appeal to authorities for immediate redress. Let every presidency town hold public meetings to memorialise Government for a public inquiry such as the Congress prays for, and let the leaders of the people do their duty by the people and work for this public cause—a cause so intimately bound up with the material progress of the country.

Yours &c.,—K. N. BAHADHURJI, M.D., Lond.
MALABAR HILL, BOMBAY, 16th January 1895.

DR. CROMBIE ON QUARTAN AGUE.

TO THE "EDITOR, "INDIAN MEDICAL RECORD."

SIR,—Will you kindly allow me most respectfully to point out what I feel is an experience quite at variance with that expressed by so excellent an authority as Dr. CROMBIE, who in his article on the fevers of India says: "*Quartan ague is so rare that it may be practically left*

out of account. I have only had to treat one case of *quartan ague* in the whole of my twenty-two years' service in India."

I have been practising for six years in the villages of the malarial district of Dinajpur, and during this time I have treated more than a hundred cases of *quartan ague*. Now I am in charge of the Raiganj Charitable Dispensary, where many patients come, who suffer from *quartan ague*. When asked, they clearly and distinctly state that they get the paroxysm every third day, the interval being seventy-two hours. I think that nearly 5 per cent. of the cases of malarial ague here are of the *quartan* type, and I believe that medical practitioners in the malarial districts of Northern Bengal, will corroborate my experiences as regards *quartan ague*.

Yours, &c., HARA KALI SEN, V.L.M.S.,
RAIGANJ, 11th January 1895.

NOTES ON THE ANNUAL RETURNS OF THE N.-W. P. AND OUDH DISPENSARIES. A SUGGESTION.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—Last year a departure was made in tabulating the surgical work of the Civil Surgeons in the above returns, by noting against each officer's name the time he had spent on leave during the year.

The desirability of this procedure cannot be doubted, as it shews at a glance what work the same officer would have done if he had *not* gone on leave. I beg to suggest, through your columns, that similar remarks may in future be added against each Assistant Surgeon's name also.

Yours, &c., ASSISTANT SURGEON, N.-W. P.

MEDICAL FEES.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—I shall feel obliged if any of your readers will kindly inform me as to the medical fees authorised to be charged per visit by Assistant Surgeons and Hospital Assistants. As far as I am aware, they vary in different localities, being modified by the pecuniary circumstances of the patients. This leads to friction during adjustment. Is there any scale laid down by Government, so that they may not fall into the error of asking more than their dues, or in the event of patients refusing to pay the prescribed fees, there may be a way open for recovering them?

Yours, &c., J. W.

ACROMEGALY AND GIGANTISM.

DR. STERNBERG concluded, at the Congress of German Physicians, that the study of the skeleton of the giant shewed that there exists a physiological and a pathological gigantism, and that the latter are cases due almost entirely to acromegaly. He thinks that gigantic growth and acromegaly can exist in the same individual. Twenty per cent. of the patients with acromegaly show evidences of gigantism, and forty per cent. of giants have acromegaly. Gigantic development predisposes to vegetative disturbances, and especially to acromegaly. Enlargement of the thymus, he thinks, is a part of the natural history of acromegaly. Thyroid feeding was productive of slight amelioration of the symptoms of the disease in one case in which it had been employed.

REVIEWS AND NOTICES.

THE THEORY AND PRACTICE OF MEDICINE. By *Frederick T. Roberts, M.D., B.Sc., F.R.C.P., Professor of Materia Medica, Therapeutics and Clinical Medicine, University College, London.* (Publisher, H. K. Lewis, 136, Gower Street, London, W. C.) Price 21s.

This well-known volume has reached its ninth edition, and may well be considered, not alone from its size—for it consists of over a thousand pages—but from its standard of excellence as a text-book, the *magnum opus* of British scientific medicine. The recent influx into India of many valuable American text-books has displaced some of our less known practical English authors. The re-appearance of ROBERTS' MEDICINE in its present well-arranged, well printed, and well-bound form, at the moderate price of 21 shillings, will bring it into great demand among practitioners and students in India and Burma. As a guide to the busy practitioner, as a work of reference to the medical scientist and as a text-book to the medical student, it will be found an inestimable boon, for which the profession at large is much indebted to its talented author and publisher.

PARKE DAVIS & CO'S PREPARATIONS.—We have received from time to time various pharmaceutical samples from this well-known firm, but we have been slow to recommend them without a protracted trial, as in the tropics drugs and their compounds undergo the most damaging deterioration during the excessive heat of summer and the excessive damp of the monsoon weather. We would now invite special attention to the perfection and practical utility of their elegant **HYPODERMIC TABLETS**, as also to the very excellent **TABLETS OF TRITURATES** for the purpose of preparing tinctures and various drug solutions. Practitioners in India would be largely profited by introducing PARKE, DAVIS & CO'S preparations into their practice in this country, as not only are they perfect and elegant, so far as artistic pharmacy can make drugs, but they are absolutely reliable in their physiological action.

Government Medical Gazettes.

GOVERNMENT OF INDIA.

H. E. the Viceroy is pleased to confer the title of Khan Bahadur as a personal distinction upon Muhammad Hussain, Senr. Hosp. Asst., S. M. D., Beng.

The Viceroy is pleased to confer the title of Rao Bahadur as a personal distinction upon Trichinopoly Venkatawami Nilamagan Pillai, Senr. Hosp. Asst., Madras Sappers and Miners; and Camalapuram Luttmiah Nayudu, Senr. Hosp. Asst., 2nd Madras Lancers.

The Viceroy is pleased to confer the title of Rai Bahadur as a personal distinction upon Lala Balha Kishan, Asst. Surgn. in Punjab.

The services of Surgn.-Capt. C. Duer, M.B., F.R.C.S., I. M. S. (Beng.), are replaced at the disposal of the Milly. Dept., from the date he was relieved of his duties at Dhulri.

Surgn.-Capt. G. B. French, 8th Beng. Infy., leave (p. a.) for four days.

Brig-Surgn. Lieut.-Col. William Roe Hooper, Civil Surgn. and Supt. Lunatic Asylum, Lucknow, is permitted to retire from the service, 15th Jan., 1895.

Brig-Surgn. Lieut.-Col. J. C. G. Carmichael, M.D., 3rd Gurkha (Mik) Regt., leave (p. a.) for eight months.

Hosp. Asst. Shamsuddin Khan, attached to the Staff Dispy., Simla, is granted three months' priv. leave, 25th Dec.

BENGAL GOVERNMENT.

Surgn.-Maj. J. French Muller made over Bandwan Jail to Surgn. Lieut.-Col. C. J. W. Meadows, 15th Dec.

Surgn. Lieut.-Col. Kali Pada Gupta, Civil Surgn. of Backergunge, leave for two months and twenty-five days, 8th Jan., 1895, and Surgn.-Capt. J. G. Jordan, on return from leave, to act as Civil Surgn. of Backergunge.

Surgn.-Capt. G. Jameson made over Rampur Boalia Central Jail to Surgn.-Maj. J. French-Mullen, 31st Dec.

Asst. Surgn. Apurba Krishna Choudhuri having passed the prescribed exam. is promoted to the 1st grade, 1st Nov.

Asst. Surgn. Nobin Chunder Dutt, of the Darbhanga Raj Hosp., leave for two months.

Asst. Surgn. Ldit Mohan Laha to have tempy. charge of the Raj Hosp. at Darbhanga, vice Asst. Surgn. Nobin Chunder Dutt.

Asst. Surgn. Kali Nath Banerjee to do superny. duty at the Med. Coll. Hosp., Calcutta, 15th Dec.

Asst. Surgn. Baroda Kanta Roy did the duties of Milly. Asst. Surgn. C. R. Bancroft at the Presy. Genl. Hosp., from 10th to 22nd Oct.

Asst. Surgn. Benode Behary Ghose to have tempy. charge of the Baidyanj sub-divn. and dispy., Buriwan Dist., vice Asst. Surgn. Broja Nath Shaha.

Asst. Surgn. Kasi Nath Ghosh to have tempy. charge of the sub-divn. and dispy. at Singur, vice Asst. Surgn. Gopal Chandra Dey allowed furlough for one year, 22nd Dec.

Asst. Surgn. Banamali Roy did superny. duty at the Chittagong Dispy. from 22nd March to 18th April, and from 4th to 18th May.

PUNJAB GOVERNMENT.

Surgn.-Capt. C. H. Bedford assumed charge of the civil med. duties of Kurram, 7th Dec., relieving Surgn.-Lieut. P. B. Haig.

Surgn.-Lieut. C. B. Prall assumed charge of the civil med. duties of Bannu, 10th Dec., relieving Surgn.-Capt. M. Fooks.

Asst. Surgn. Abunashi Ram, in charge of the Karnal Dispy., assumed charge of the civil med. duties of Karnal, in addition to his own, 8th Dec., relieving Asst. Surgn. W. Marchant, who assumed charge of the civil med. duties of Shahpur, 18th Dec., relieving Dr. J. A. Fluk.

Hosp. Asst. Imam-ud-din from Western Jumna Canal Dispy. Safidon, to the Paudri Canal Dispy. 29th Nov. vice Hosp. Asst. Uttam Chaul transferred to the Safidon Canal Dispy.

Hosp. Asst. Amir Baksh, City (old) Dispy., Amritsar, three months' priv. leave, and was relieved on the 18th Dec. by Hosp. Asst. Sawan Mal, transferred from Chenab Canal Dispy., Gujranwala Dist.

Hosp. Asst. Loharia Ram, on genl. duty at the Mayo Hosp., Lahore, to the Ferozepore Dispy., 18th Dec.

Asst. Surgn. Radha Kishan resumed charge of the Gurdaspur Dispy. on the 29th Nov., relieving Asst. Surgn. Fazl-ud-din.

Hosp. Asst. Yusuf Ali, at present in charge of the Para Chinara Dispy., Kurram, having passed the prescribed exam. in Pushtu, is entitled to an extra allowance of Rs. 5 per mensem from the 8th Dec. and as long as he is employed in Pushtu-speaking tracts.

Asst. Surgn. Ram Narain (I), Asst. to the Civil Surgn. Delhi, two months' priv. leave, and was relieved on the 18th Dec. by Asst. Surgn. Meher Chand (I), transferred from Lahore.

Hosp. Asst. Mutehab Khan, on genl. duty, Rawalpindi Civil Hosp. to the Fatahjang Dispy., 16th Dec. vice Hosp. Asst. Govenindan Das, transferred to the Gujra Khana Dispy., 17th Dec., vice Hosp. Asst. Moha Ram, transferred to the Rawalpindi Civil Hosp. for genl. duty.

Asst. Surgn. Jogendro Nath Biswas, Offg. Depy. Med. Offr. Lahore Central Jail, to the Chakwal Dispy., Jhelum Dist., 10th Nov.

Asst. Surgn. Guran Ditta Mal, Asst. Chemical Examr, Panjab, and Lecturer on Mikewery to Hindustani Class, Med. School, Lahore, one month's priv. leave, 17th Dec.

Asst. Surgn. Jhangli Ram to do genl. duty at Battala, Gurdaspur Dist., 24th Nov.

Hosp. Asst. Ghulam Rasool, on genl. duty at Battala, Gurdaspur Dist., to the Mardian Dispy., Pathwar Dist., 1st Dec., relieving Hosp. Asst. Jawala Shah, placed on special duty with Balraj Delimitation Commission.

First Class Hosp. Asst. Maha Narain having passed the English Qualification Exam., is entitled to the higher rate of pay of his grade from the 10th Dec.

On being relieved at the Mong Dispy., Gujrat Dist., Hosp. Asst. Khair-ud-din was transferred to Dera Ghazi Khan Police Hosp., 30th Nov., relieving Hosp. Asst. Moti Singh, retired.

Surgn.-Capt. H. Fooks made over Bannu Jail to Surgn.-Lieut. C. B. Prall, 10th Dec.

Surgn.-Maj. C. J. Bamber made over Rawalpindi Jail, 20th Dec.

Surgn.-Maj. L. T. Young made over Umballa Jail to Asst. Surgn. Khazan Chand, 24th Dec.

Hosp. Asst. Ghulam Kasul was, on being relieved from suspension, transferred from Karnal to Bhatala, Gurdaspur Dist., for fever duty, 11th Oct. to 24th Nov.

Student Khuda Baksh of the Lahore Med. School, having passed his final exam., is admitted into the service as a Hosp. Asst. of the 3rd class, 21st Dec., and apptd. to genl. duty at the Mayo Hosp., Lahore.

Asst. Surgn. Sodhi Karm Singh, on being relieved of charge of Egerton Hosp., Peshawar, was transferred to the Gujranwala Dispy., 30th Dec.

Asst. Surgn. Farma Nand, Gujranwala Dispy., one month and five days' priv. leave, 29th Dec.

Hosp. Asst. Chajmal Das, having been relieved from suspension at Dera Ghazi Khan, was transferred to the Chenab Canal Dispy. at Killa Ram Kaur, Gujranwala Dist., 8th Dec., relieving Hosp. Asst. Sawan Mal.

Hosp. Asst. Sant Singh, doing genl. duty at Ludhiana, to the Burka Kalan Dispy., Jullundur Dist., 25th Dec., relieving Hosp. Asst. Ram Jas, apptd. to genl. duty at Jullundur.

Hosp. Asst. Umar Khan resumed charge of the Teri Dispy., Kohat Dist., 22nd Dec., relieving Hosp. Asst. Chirag-ud-din.

Asst. Surgn. Fazl-ud-din, doing genl. duty at the Mayo Hosp., Lahore, to the Egerton Hosp., Peshawar, 24th Dec., relieving Asst. Surgn. Sodhi Karm Singh.

Hosp. Asst. Nawab Khan resumed charge of the Gomal Pass Dispy., Dera Ismail Khan Dist., 21st Dec., relieving Hosp. Asst. Dasrundi Khan, apptd. to the Kulachi Dispy., Dera Ismail Khan Dist., 24th Dec., *vice* Hosp. Asst. Alam Shah, granted three months' priv. leave.

Asst. Surgn. B. Phillips, doing genl. duty at Rawalpindi, to the Dandot Colliery Dispy., N.-W. Ry., 15th Dec., relieving Asst. Surgn. Dewan Ali.

Asst. Surgn. Diwan Ali, Dandot Colliery Dispy., N.-W. Ry., to the Pindigheb Dispy., Rawalpindi Dist., 22nd Dec., relieving Asst. Surgn. Daljant Singh Khanka, whose services have been placed at the disposal of the Foreign Dept. for employment in the Jeypore State.

Hosp. Asst. Amir Khan, doing genl. duty at the Mayo Hosp., Lahore, to the Karnal Dispy., 25th Dec., for genl. duty.

MADRAS GOVERNMENT.

Brig.-Surgn. Lieut.-Col. J. North, I. M. S., 1st Madras Lancers, leave for one year.

Surgn.-Lieut. E. H. Sharman, I. M. S. (Madras) to be Offg. Med. Offr., 6th Infantry, H. C., *vice* Surgn.-Lieut. G. Bidle, on furlough.

Surgn.-Capt. C. A. Johnston, I. M. S. (Madras) to be Offg. Med. Offr. 1st Lancers H. C., during the absence of Surgn.-Major. C. Mallins, M.D., apptd. to offg. as Depy. San'y. Commr., Madras, 6th Dec.

Brig.-Surgn. Lieut.-Col. J. F. Sargent, I. M. S. (Madras) Med. Offr. 2nd Lancers, to be Med. Offr. 4th Lancers, H. C., *vice* Surgn.-Major. G. J. Kellie, who exchanges, 1st Dec.

Surgn.-Capt. E. H. Wright, I. M. S. (Madras) to be Offg. Med. Offr. 3rd Infantry, H. C., *vice* Surgn.-Maj. H. G. L. Wortabet, M.D., on furlough, 9th Nov.

BOMBAY GOVERNMENT.

Transfers of Hosp. Assts.—Udhev Deoji Powar, from fair duty, Alandi to genl. duty, Poona, 29th Nov.

Shivaji Paudu Jadav, from genl. duty, Godhra, to Hialol Dispy., 19th Nov.

Balkrishna Pandurang, from genl. duty, Godhra, to Bombay, 25th Nov.

Ebrahimkhan, from genl. duty, Aden, to Bombay, 3rd Dec.

Gunesh Vinayek, from Bhadgaon to Khanspur Dispy., 27th Nov., *vice* Narayan Vithal, transferred.

Chhaganlal Atmaram, from genl. duty, Kaira, to Nadiad Dispy., *vice* Ramsing, transferred to Dohad Dispy., 27th Nov., *vice* Asst. Surgn. D. E. Kothavala transferred.

Maneklal Harjivan Vyas, from genl. duty, Godhra to Kapadvanj Dispy., 3rd Dec., *vice* Abraham Shalum, transferred.

Wadilal Kesharilal, from genl. duty, Patana, to Patan Dispy., 27th Nov., *vice* Mohanlal Nanakram, on leave for three months.

Manikum Subrayam, from Civil Hosp., Bijapur, to Supa Dispy., 30th Nov., *vice* Dattatraya Gunesh, transferred.

Baberbhai Chhotabhai, from genl. duty, Ahmedabad, to Rajkot, 25th Nov.

Govind Balkrishna, from genl. duty, Poona, to Ratnagiri, 22nd Nov.

Mukund Sudashtiva, from genl. duty, Ahmedabad, to Surat, 25th Nov.

Krishnaji Dattatraya, from genl. duty, Poona, to Belgaum, 20th Nov.

Kasalnath Hari, from genl. duty, Poona, to Thana, 19th Nov.

Pandharinath Bhawrao, from genl. duty, Poona, to Dhulni, 18th Nov.

Yeshwant Balkrishna, from genl. duty, Poona, to Thana, 17th Nov.

Wasulver Gungalher, from genl. duty, Poona, to Belgaum, 21st Nov.

Parbhuram Tuljaram, from genl. duty, Ahmedabad, to Surat, 25th Nov.

Ramchandra Narasingh, from genl. duty, Poona, to Nasik, 22nd Nov.

Bhugvandas Jivanram, from genl. duty, Ahmedabad, to Rajkot, 25th Nov.

Bhimaji Krishna, from genl. duty, Poona, to Dharwar, 22nd Nov.

Yeshwant Galmooji, from genl. duty, Poona, to Nasik, 21st Nov.

Krishnaji Ramchander, from genl. duty, Poona, to Dharwar, 24th Nov.

Pranshanker Khushalrai, from genl. duty, Ahmedabad, to Kaira, 26th Nov.

Abdul Latif, from genl. duty, Poona, to Karwar, 21st Nov.

Reuben Sudkell, from N.-W. Ry. Hosp. to Kotri, Umartkot-Fachbadra Ry. survey, 1st Nov.

Hiranand Nanumal, from genl. duty, Shikarpur, to Mehar Dispy., 14th Nov., *vice* Khushaldas Khemchand, transferred to Kotri-Rohri Railway Survey.

Chubermal Santiasa, from Civil Hosp., Hyderabad, to Schwan Dispy., 13th Nov., *vice* Tukaram Pandernath, transferred to Kotri-Rohri Ry. Survey.

Mulchand Jhematmal, from genl. duty, Hyderabad, to N.-W. Ry. Hosp., Kotri, 16th Nov.

Kundanmal Karamchand, from genl. duty, Hyderabad, to Hyderabad-Umartkot State Ry., 16th Nov.

Baharsing Toursing, from genl. duty, Hyderabad, to Karachi, 17th Nov.

Pessumal Wadhmal, from genl. duty, Hyderabad, to Jacobabad, 16th Nov.

The undermentioned Asst. Surgns., I.S.M.D., 2nd grade, passed the exam. qualifying them for promotion to 1st grade:—Daniel William Adolphus Gillespie, William Henry Cabral, John Greahy, William Frederick Barnett, Albino Graciano Alphonso, Joseph Alexander Cordeiro, Mathew Lewis Cabral, and Louis Xavier DeSilva, 15th Oct.

The undermentioned Milly. pupils have qualified themselves for the grade of Asst. Surgns., I.S.M.D., 3rd class, at the Grant Med. Coll. for the Bengal Presidency, and are transferred to that Presidency:—John Vincent James, James William Lawrence, Reginald Henry Willick Hart, William George St. John Hussey, Walter Arthur Clifford Netscher Thomas Henderson Brooks, Charles Mullins, Donald Day Stewart, Charles Samuel Anthony Reginald Brown, Ronald Mackinnon, Henry Osmond Bazely, William Fitzallan Parrott, Charles Wiltshire Maine, and Hugh Norman Stewart.

The undermentioned Hosp. Assts passed the exam. qualifying them for promotion:—2nd grade Solomon Ezekial, Ittoo Chowan, Luxumun Khundoji, Rahmin Shalomji, Ramji Khundoji Kudum, Luxminarayen Jethabhoy, Hamidoolah Azimtoolah, Shivrani Naidoo, Shaik Ali Shabash, Ballaram Lingoo, Ramchandra Vasudera, Gunesh Sudashtiva, Dasayyah Vithoo, Vithu Bapu Sawant, Succoram Babaji:—3rd grade, Bhawoo Bajirao, Ramchander Govind, Mahadeo Luxuman; Civil Branch, 2nd class, Keshow Govind, Chaturji Narayan, Nasarwanji Pantonji.

Surgn.-Maj. R. W. S. Lyons, M.D., to act as Prof'r. of Medicine and Clinical Medicine and Therapeutics, Grant Med. Coll., *vice* Surgn.-Maj. R. Manser, M.D.

Surgn.-Lieut.-Col. Patrick Murphy, M.D., I. M. S., is permitted to retire from the service, 17th Jan'y, 1893.

Asst. Surgn. J. E. White is permitted to resign the service at his own request.

Asst. Surgn. Navroji Kavaji Kalyanvala, L.M. & S., priv. leave for two months, 29th Nov.

Asst. Surgn. B. E. Ghaswalla, L.M. & S., 1st Asst. Chemical Analyst to Govt., has been apptd. as a temp. measure, to act as Demonstrator of Anatomy in the Grant Med. Coll., in addition to his own duties, from 8th Dec., *vice* Asst. Surgn. N. K. Kallianwalla, L.M. & S.

Miss A. M. Benson, M.D., apptd. to be 1st Physician, Pestanj Hormasji Kama Hosp. for women and children, took charge on 12th Nov.

CENTRAL PROVINCES GOVERNMENT.

Civil Hosp. Asst. Syed Sallar, doing duty under orders of the Civil Surgn., Raipur, is apptd. to the Jail and Police Hosp., Chhindwara, *vice* Civil Hosp. Asst. Bashiruddin, apptd. to the Deori Branch Dispy., Sangor Dist., *vice* Civil Hosp. Asst. Pratapsing, directed to duty under orders of the Civil Surgn., Sambalpur.

Two months' sick leave is granted to Civil Hosp. Asst. Ram Sahai in extension.

Civil Hosp. Asst. Chunder Bhan, of the Jail and Police Hosp., Narsinghpur, is posted to the Banda Branch Dispy., Sangor Dist., *vice* Civil Hosp. Asst. Ram Lal posted to the Behli Branch Dispy., *vice* Civil Hosp. Asst. Saadut Hussain, posted to the Jail and Police Hosp., Narsinghpur.

Asst. Surgn. Omesh Chander Mitter resumed charge of his duties at the Omaria Colliery on the 17th Dec.

On being relieved by Asst. Surgn. Omesh Chunder Mitter, Asst. Surgn. Gopal Chander Ghose, to act as Sany. Inspr. in the Ohhattagurh Divn.

Relieved by Civil Hosp. Asst. Kunj Behari Lal on return from leave, Civil Hosp. Asst. Sitaram Roupchand, temply. attached to the Harda Branch Dispy., Hoshangabad Dist., is apptd. to the Sohagpur Branch Dispy., Hoshangabad Dist., *vice* Hosp. Asst. Balaji Baliram, apptd. to the Jail and Police Hosp., Hoshangabad.

Three months' priv. leave is granted to Civil Hosp. Asst. Syed Gulam Nabl. of the Central Jail Hosp., Raipur.

Civil Hosp. Asst. Gunga Pershad Singh, going duty under orders of the Civil Surgn., Bilaspur, is temply. posted to the Central Jail Hosp., Raipur, *vice* Civil Hosp. Asst. Syed Gulam Nabl.

N.-W. P. AND OUDH GOVERNMENT.

Surgn.-Maj. J. Sykes, Civil Surgn., Mussoorie, priv. leave for one month, 15th Jan. 1895.

Asst. Surgn. Mul Raj, of the Salar Dispy., Fyzabad, furlough for two years, 1st Feby. 1895.

Surgn.-Maj. C. Seymour, Station Hosp., Landour, to the civil med. charge of Mussoorie, in addition to his milly. duties, *vice* Surgn.-Maj. J. Sykes.

Surgn.-Capt. S. H. Henderson, Offg. Supdt., Allahabad, on being relieved by Surgn. Lieut.-Col. G. C. Hall, to office, as Civil Surgn., Fatehpur.

Surgn.-Lieut. A. O. Hubbard, I. M. S., to the civil med. charge of Almora, in addition to his milly. duties, 13th Dec.

Dalip Singh, a passed student of the Lahore Med. Coll., is apptd. to the Civil Med. Dept. of these Provinces as a 3rd grade Asst. Surgn., 28th Dec., and placed on reserve duty at Lucknow.

Asst. Surgn. Trishita Nath Singha, on reserve duty at Jhansi, to the charge of the Lalitpur Dispy., Jhansi Dist., *vice* Asst. Surgn. Ram Charan, granted priv. leave.

Surgn. Lieut.-Col. G. C. Hall, Suplt., Central Prison, on return from furlough, to the charge of the Central Prison, Allahabad.

BURMA GOVERNMENT.

Surgn.-Maj. R. E. S. Davis, M.B., made over and Surgn.-Capt. R. H. Castor, M.B., assumed, charge of the duties of the Secy. to the Inspr.-Genl. of Jails, Burma, 18th Dec.

Dr. H. J. Augustine made over, and Asst. Surgn. Thomas Kiddle assumed, charge of the Civil Surgency., Myitkyina, 4th Dec.

Surgn.-Capt. T. W. Stewart made over, and Surgn.-Capt. C. W. Johnson assumed, charge of the Civil Surgency. of the Meiktila Dist., 12th Dec.

Hosp. Asst. Rama Chandra Succaram Deshmookha left Civil Hosp., Pymmana, and assumed charge of the Ry. Dispy., Yamethin, 9th Dec.

Hosp. Asst. Nurdyan assumed, as an additional duty, charge of the Civil Dispy., Letpadan, Tharrawaddy Dist., 14th Dec. *vice* Hosp. Asst. Ashutosh Basu.

Hosp. Asst. Ram Lal, on leave for three months, left Civil Dispy., Kyauktan, Pegu Dist., 12th Nov.

Hosp. Asst. Sandhe Khan left Police Hosp., Bhamo, and assumed medical charge of the No. 1 South-Eastern Escort, Bhamo, 1st Dec.

Hosp. Asst. Muhammad Zaman Khan left Police Hosp., Mogok, and assumed charge of the Civil Hosp., Mogok, Ruby Mines Dist., 6th Dec.

Hosp. Asst. Krishna Hurry, left genl. Hosp. and assumed charge of the Civil Dispy., Maymyo, Mandalay Dist., 7th Dec.

Hosp. Asst. Riazuddin left Outpost Hosp., N'krong and assumed charge of the Outpost Hosp., Sima, Myitkyina Dist., 19th Nov.

Hosp. Asst. Uma Chunder Chuckerbutty left Police Hosp., Bhamo, and assumed medical charge of the No. 3 Koukwa Escort, Bhamo, 30th Nov.

Hosp. Asst. Mahomed Sheriff, on return from leave, assumed charge of the Police Hosp., Mogok, Ruby Mines Dist., 5th Dec.

Surgn.-Capt. R. H. Castor made over, and Surgn.-Capt. T. W. Stewart assumed, executive and med. charge of the Yamethin Dist. Jail, 15th Dec.

Surgn.-Capt. R. H. Castor made over, and Surgn.-Capt. T. W. Stewart assumed, charge of the Civil Surgency., Yamethin Dist., 15th Dec.

Asst. Surgn. F. Bradley made over, and Mr. H. E. Wells, M.B., C.M., assumed, charge of the Civil Surgency., Ruby Mines Dist., 15th Dec.

Hosp. Asst. D. de Souza assumed charge of the Police Hosp., Bhamo, on special escort duty, 21st Nov.

Hosp. Asst. D. de Souza left Police Hosp., Bhamo, and assumed med. charge of the No. 4 North-Eastern escort, Bhamo, 12th Dec.

Hosp. Asst. Syed Abdul Khader assumed charge of the Police Hosp., Bhamo, 29th Nov.

Hosp. Asst. Radha Nath Singh assumed charge of the Outpost Hosp., Pinka, Mogaung Sub-divn., 18th Nov.

Hosp. Asst. Bistoo Charu Das left Police Hosp., Mogok, and assumed charge of the Civil Hosp., Mogok, Ruby Mines Dist., 23rd Oct.

Hosp. Asst. Bistoo Charu Das having passed an exam. in English on the 7th Dec., is entitled to the allowance for the same.

Hosp. Asst. Abdul Wahid assumed charge of the Police Hosp., Mogaung, 21st Dec.

Hosp. Asst. Rajchunder Kur assumed charge of the Civil Hosp., Kindat, Upper Chindwin Dist., 2nd Dec.

ASSAM GOVERNMENT.

Privilege leave for two months is granted to Hosp. Asst. Ram Lochan Das, in charge of the Lakhimpur Dispy., Goalpara Dist., 19th Dec.

Hosp. Asst. Mahim Chandrn Datta, in tempy. charge of the Krishnai Dispy., Goalpara Dist., is apptd. to the charge of the Lakhimpur Dispy., in that dist., *vice* Hosp. Asst. Ram Lochan Das, 19th Dec.

DOMESTIC OCCURRENCES.

The charge for inserting a Domestic Occurrence is Rs. 1 for subscribers and Rs. 2 for non-subscribers, which should be forwarded in stamps with the announcement.

BIRTHS.

GIBBONS.—On 7th Jan. 1895, at Sealdah House, the wife of Surgn.-Maj. J. B. Gibbons, of a daughter.

MANN.—On 'Xmas Day, 1894, at Lucknow, the wife of Asst. Surgn. H. V. Mann, of a son (premature).

DEATHS.

ATKINS.—On 2nd Jan., 1895, at Fatehpore, of abscess of the liver, Charles J. Atkins, Civil Surgn., aged 47 years. (Deeply regretted).

EDGE.—On 5th Jan., at 18, Staveley Road, Poona, George, infant son of Surgeon Lieutenant-Colonel and Mrs. Edge, aged 4 days.

NOTICES TO CORRESPONDENTS.

R. P. B. (Pachbadra).—Dr. Elliott's article has been sent us for publication, and will appear in our next issue. You will then have an opportunity of reading his views. The viper heads sent will be forwarded to London as you request.

W. H. B. (Allahabad).—Many thanks for the report. It will appear in our next number.

Jurula Parahad (Lahore).—We have received the pamphlet, and thank you much for it.

W. H. H. (Madras).—Retired Warrant Medical Officers, according to the order of Government, may use the title of the new Warrant if they apply to Government to be placed on the Reserve List for active service. All Warrant Medical Officers are *qualified* practitioners, and are entitled to grant medical certificates.

Hopeless.—Kindly quote the Government of India Order in full, disallowing a free pass to an attendant on a sick hospital assistant.

J. N. G., D. M., J. P., R. A.—Many thanks for your papers. They will find early insertion.

J. M. (Bombay).—We are not aware of the identity. Many thanks for your trouble.

S. A. (Fatehpur).—You do not say whether you would wish your son to enter as a Civil or as a Military medical pupil. The fullest information is to be found in "The Medical Register and Directory of the Indian Empire," obtainable from the Manager of this office.

T. A. (Madag).—Your paper is not yet received.

J. R. H. (Lucknow).—You are admissible to the Association.

Congress Contributors.—We sincerely thank the many Congress contributors who have very kindly sent us their contributions for publication in the *Record*.

ACKNOWLEDGMENTS.

We acknowledge receipt of the following with thanks:

Journals.—Lancet—British Medical Journal—Birmingham Medical Review—Medical Times and Hospital Gazette—Temperance Record—Universal Medical Journal—Medical Age—Medical Bulletin—Medical World—Good Health—Medical Brief—Australasian Medical Gazette—American Lancet—Toledo Medical Compend—Chemist and Druggist—Canadian Practitioner—Indian Medical Gazette—Ceylon Medical Journal—Medical Reporter—Nursing Record—Clinical Journal—Journal of the American Medical Association—Medical News—Sanitarian—Medical Week—Indian Medico-Chirurgical Review—New York Medical Record—New York Medical Journal—Edinburgh Medical Journal—Virginia Medical Monthly—Pacific Medical Journal—Provincial Medical Journal—Ganjina Tibabat—Gaillard's Medical Journal—Calcutta Journal of Medicine—Sculpel—Indian Journal of Pharmacy.

EPIDEMIC OF ICTERUS.

KRAMER observed an epidemic of icterus in a small town in Denmark, forty-two cases occurring within two months, generally affecting children between 5 and 6 years of age. Many other cases escaped medical observation. The disease was characterised by jaundice, great prostration, enlargement of the liver, and pain in the hepatic region. Convalescence was somewhat slow, but no deaths or complications occurred. The origin of the epidemic was unknown.

Original Articles.

IS STRYCHNINE AN ANTIDOTE TO COBRA POISON.

By SURGN.-LIEUT. R. H. ELLIOT, M.B., B.S., Lond.,
F.R.C.S., Eng., D.P.H., Camb. I. M. S.

We are familiar with the statement that history repeats itself, and perhaps in few branches of science is this adage so well illustrated as it is in the past and present of snake poisoning. One vaunted cure after another has come before the profession and the public only to spend its short day and then bubble-like to burst, leaving no trace behind it on the world of science.

I have been asked why I have not been content to stand aside and watch the fate of this strychnine remedy, secure in the knowledge that if it be a bubble, bubble-like it must burst, while if it be all that has been claimed for it, it must and will remain a most enduring beacon founded on a bed-rock of solid fact to throw light through all time over the troubled face of the ever-changing sea of medical opinion.

Were I confident that the new remedy would run its course doing only good, or even doing more good than harm, I would gladly stand aside, but neither you nor I can blind ourselves to the fact that this line of treatment is fraught with the gravest danger to the lives of men, women and children. Already we have on record cases which suggest the very worst possibilities, and those too in *Thanatophidia*-bitten patients, but what of the great army of the scorpion-stung, the rat-bitten, the thorn-pricked, and others, who coming under treatment in a state of collapse, the result of fear, may be subjected to the agonies, if not the death of strychnisation, by an over-zealous and well-meaning practitioner.

Nay, more should it fall to the lot of any of us to render agonised the closing moments of some valued and valuable life, should we soon forgive ourselves, and even if we did so, would the patient's friends be equally lenient? I think not.

It seems hardly necessary to remind such an audience as I have the privilege of addressing to-day of the past history of the strychnine treatment of snake-bite.

Australia, which 25 years ago in the person of Dr. HALFORD pressed on us the acceptance of the ammonia cure, and which indignantly received our critical rejection of Dr. HALFORD's treatment, Australia I say to-day has left the ammonia cure behind and as confidently as ever presses on us a snake-bite-cure, but now a new one, namely, strychnine. I do not pretend to say that strychnine and ammonia are not antidotal to the bites of Australian snakes, though I must say that the evidence is to my mind far from convincing, but I will bear you all with me when I say that we in Madras at least have been far from satisfied with the reported cures that have, from time to time, been published in the Indian papers.

Two cases were brought up before our Branch of the British Medical Association some months ago, and the suggestion was then thrown out that if only we could

carry out some experiments on animals, much might be done to clear up our doubts and to place the matter on a more satisfactory basis. With an excellent zoological laboratory and trained assistants at my disposal, the opportunity to do something was too tempting to be resisted, and the work that I put before you to-day has been the outcome of the suggestion I referred to.

The object that I had before me was to ascertain the value of strychnine as an antidote for snake poisoning, and two courses seemed to me to be open to the worker in this field.

The first was to experiment on the lower animals.

The second was to experiment on man.

To the latter procedure we may apply the more euphemistic term clinical observation. It must be remembered, however, that the grounds on which our action is based are theoretical, so far as Indian snakes are concerned, that strychnine is a dangerous drug, and that it is often very difficult to determine whether any case is one of *Thanatophidia* bite or not.

Bearing such important considerations in mind we cannot, I think, refuse to accept the term *experiment* for the Strychnine treatment of man.

Surely at the outset of such an enquiry as the one before us, the more justifiable course to pursue is to experiment on animals. Should the answer to these experiments be a favorable one, we may boldly proceed to try our remedy on man.

I propose to give you first the results of my experiments on the cobra poisoned animals, and later to analyse and discuss the reported cases of the strychnine treatment of snake-bite in man.

I am well aware that Dr. MUELLER has objected to receive any conclusion drawn from experiments on animals.

Before dealing with his objection, let me point your attention to his letter, dated 28th June 1890, in which in writing to the Chief Secretary of Victoria, he quotes certain experiments on animals in Russia which had proved favorable to his conclusions. These experiments he there brings forward as a strong argument in favor of his theory, and yet when subsequent work points the other way, Dr. MUELLER declines to own it.

His objections are based on two grounds:—

(1) That the experiments previously conducted were carried out on dogs, and that one could not argue direct from one class of vertebrates to another, even though both were mammals; and

(2) That between the nervous system of man and the lower animals there is 'only a functional analogy which has been mistaken for a complete identity.'

I quote from the *Indian Medical Record* of 16th September 1892, which contains a very friendly criticism on Dr. MUELLER's account of '86 years' work on snake poison.

Before entering on my own methods, allow me very briefly to discuss these objections.

The first of them had occurred to me at the very outset of my work, and I therefore determined not to limit myself to one or even to two or three sets of vertebrate animals, but to choose common animals which would as

thoroughly as possible represent the vertebrate kingdom, and especially the mammalia.

With this end in view the following animals were selected:—Frogs, lizards, ducks, fowls, hares, monkeys, pigs, dogs, goats, guinea-pigs.

Any one possessing even the most superficial knowledge of comparative anatomy must admit that the above list is very fairly representative of the vertebrate kingdom, and especially of the mammalia.

I argued and I think no one will dispute my contention, that if experiments on these various animals gave one and the same answer, one might fairly believe that man would give the same.

If I am wrong in this conclusion what, may I ask, becomes of our belief in the doctrine of evolution, for if we admit that man and the lower animals have had a common source and that many of these in the list before you possess the closest affinities with ourselves, surely, it is no presumption to believe that influences which affect these animals one and all in the same manner, will affect us similarly under similar circumstances.

Even if you reject the theory of evolution, the facts of comparative anatomy and physiology strongly support the same argument.

Now to deal shortly with the second objection. I for one cannot accept the statement that between man and the lower animals there is merely a functional analogy. By the term 'merely a functional analogy' I understand Dr. MULLER to mean that the nervous systems of man and animals are constructed to perform the same function, and that they have nothing more in common.

No one will contend for a moment that there is absolute identity between the nervous systems of two animals even of the same species, be they man or beast, but I maintain most strongly that not only is there a functional analogy, but that there is an anatomical analogy; a physiological analogy; a pathological analogy; a clinical analogy; a therapeutic analogy, and in that there is every kind of analogy, between the nervous systems of man and the lower vertebrata.

Over the anatomical analogy it would be a waste of time to stay. It is too familiar to us all. As for a therapeutic and a physiological analogy, one would have thought that the researches of BRUNTON and other well-known workers, had long ago removed it from the land of speculation. Is not a great deal of our medicine and pathology to-day based on it?

It may reasonably be asked, however—What evidence is there of this universal analogy between man and the lower vertebrata in their reactions to the two poisons before us? In other words, do we find that cobra poison and strychnine respectively, produce closely similar manifestations throughout the vertebrate kingdom?

In order to answer this let us compare the effects of these poisons on the animals which have been experimented on, with the well-known effects of the same agents on man. They will be found to be practically identical.

A review of the strychnine control experiments recorded, will show that the first symptom of strychnisation is a general brace-up of the nervous system. The

animal in fact is on the *qui vive*, a few moments later and it becomes alarmed while its movements tend to be spasmodic. It seems unable to stand comfortably and gives one the impression that it is walking on hot bricks, suddenly a convulsion, either opisthotonic or emprosthotonic, more commonly the former, throws it down. Clonic and tonic convulsions now alternate, respiratory spasm is severe the embarrassment of the respiratory centre is shown in the general lividity, and further in the very rapid breathing during the intervals of spasm.

The least stimulus, such as a sound or touch, brings on a fit in an animal which, if left alone, might lie quite still. The convulsions are attended with severe pain, and the patient dies usually in respiratory spasm or more rarely exhausted by frequent spasms. Should a fatal issue be averted, the animal rapidly recovers, the convulsive stage passing into a sleepy condition in which the nervous system seems profoundly exhausted, but in which I have never seen an animal die. So much for strychnine in animals. I think you will admit that the picture I have endeavoured to draw from carefully recorded notes on animals would apply equally well to man.

Now as to cobra poison:—

In frogs and lizards the only points noticeable were, that the animal showed signs of malaise, paralysis rapidly supervened, spasms usually occurred, and life was extinguished.

Speaking generally of the mammalia experimented on, one might say that the stages passed through are best represented by the words off-repeated in the notes—Walking, soon sitting down, lying down, dying.

The earliest symptoms noticed are drowsiness and loss of control over the limbs, especially the hind limbs. The animal no longer moves about, and it evidently prefers to be left alone. When disturbed, it soon settles down again. After a short interval the sitting posture is forsaken and soon the patient is found lying helplessly prone, paralysed and dying.

The respiration toward the end is slow but not labored. At this stage the shallow breathing, livid color and general condition of nervous failure suggest to me the patient we have all of us seen at one time or another brought in from a severe railway smash. The all-round nervous exhaustion exhibited in such a case from loss of blood is here repeated as a consequence of general poisoning of the nervous centres. Like the railway patient alluded to, the cobra poisoned animal retains his consciousness almost to the last.

Then comes the end, often ushered in by a little shudder, a clonic spasm of limbs, in no wise comparable with the strychnine convulsion, and the curtain drops.

Salivation was a very common, if not a constant feature of the case in the mammals experimented on. I can only regret that its very commonness led to its escaping notice in the recorded tables. In dogs, goats, pigs and monkeys as well as in the birds, it was a practically unvarying symptom.

An examination of the subcutaneous tissue at the seat of the injection showed an extravasation evidently of an inflammatory nature around the seat of lesion.

In monkeys two additional symptoms were present, and to these I wish especially to direct your attention. In these animals the earliest sign of cobra poison is a drooping of the upper eyelids. This becomes so marked in time that the animal tilts his head back, and rolls his eyes down in order to see out of his pupils. This drooping is evidently paralytic. The remaining symptom is a condition frequently referred to in the notes on monkeys as *drunkenness*. The animal loses its power of co-ordination and staggers about with an extremely drunken giddy look. In one case the monkey seemed to suffer from the optical delusion that a rope was before it. This it tried to reach.

Turn now to WALL's able description of a human being suffering from the results of a snake-bite, and we have an exact repetition of the above story. You will find his account in WALL'S Indian Snake Poison, pp. 2—4 and pp. 10—15. See also RICHARDS' Landmarks of Snake-poison Literature, pp. 134—235, and the Proceedings of the Snake-poison Commission of 1873 and 1874, pp. 36—41.

Most striking are WALL's allusions to the early drooping of the eyelids and to the feeling of drunkenness the patient complained of. He goes on to say that the latter symptom will probably never be elicited in animals on account of their lower intelligence not enabling them to communicate it. *Est humanum errare*, and in this particular WALL has justified the old saying.

Lastly, one may add that an animal suffering from a heavy dose of cobra poison does not necessarily shew the drunken stage, but passes rapidly from drowsiness with drooping eyelids into a rapidly fatal end, attended with shivering convulsion.

These and other points that time forbids us to dwell on will, I think, establish my contention that there is a very close analogy between the various mammalia including man, in their behaviour to the two poisons we are discussing.

With these facts before you, I think I shall carry you with me when I say that this analogy is not merely one of function, but that it embraces symptomatology, pathology and therapeutics, not to speak of anatomy and physiology.

Starting from the basis, that man and the lower mammalia react alike to the two poisons we are considering, let us *1st* investigate the effect of the two poisons when at work together on animals, and *2nd* let us in like manner study the results of the similar experiments on man.

With this end in view, I will now invite your attention to the results of my recent experiments. Of almost all of them, some of you have been witnesses, and you are aware that throughout I have courted the utmost professional publicity and criticism.

That the results so obtained are of value for deductive purposes I think I may now safely assume that you all believe.

Forgive my digressing for one moment to express the regret that one cannot but feel, when one sees well-meaning but alas! mistaken people bitterly opposing all vivisection except that carried out on human beings. Such a position, in my mind, is untenable.

It is necessary at the outset to describe shortly the technique I have employed.

All the experiments have been carried out with the binocellate cobra (*Naja tripudians*); but I hope at a later date to carry out a similar series of experiments with the other poisonous snakes of India.

The cobra was chloroformed in a large glass bottle. It quickly died and was then removed, and the two poison glands dissected out. From these glands the poison was squeezed out and allowed to fall into watch glasses. A number of these glasses were ready before-hand, and each glass was labelled according to the number of drops it contained.

These were put away in batches carefully labelled with the date, &c.

The poison rapidly dries, solid.

When required for use, a small quantity of saline solution is added to the dried poison, and this is then dissolved, drawn up into the syringe and subcutaneously injected in the abdomen.

During my earlier experiments I injected into one thigh, but gave this up in favor of the subcutaneous tissue of the abdomen, as the spurious condition of paralysis produced in the injured thigh was very confusing.

MR. JONES, Professor of Physics at the Madras Presidency College, very kindly weighed for me a number of drops of cobra poison taken at random from those in actual use.

These drops were first allowed to dry. I will read you MR. JONES' report.

"The following are the masses of the substances submitted:—

| | | | | | | |
|-----|--------|---------|---|-------|-------|-------|
| (1) | 0.011 | Grammes | — | 1/4th | Grain | about |
| (2) | 0.009 | " | — | 1/4th | " | " |
| (3) | 0.0097 | " | — | 1/4th | " | " |
| (4) | 0.008 | " | — | 1/4th | " | " |
| (5) | 0.007 | " | — | 1/4th | " | " |
| (6) | 0.007 | " | — | 1/4th | " | " |
| (7) | 0.007 | " | — | 1/4th | " | " |
| (8) | 0.009 | " | — | 1/4th | " | " |

The differences in the masses of the drops may be ascribed to—

- (1) Unsteadiness of the support.
- (2) Unsteadiness in the rate of flow of the liquid out of the gland.
- (3) Alteration in the surface-tension of the liquid, assuming that the gland was held in the same position, and the liquid was that of the same density throughout.

After keeping two of the substances in desiccators for two days, I found very little alteration on weighing again."

In the tables of experiments I have for convenience sake spoken of these drops as minima, though strictly speaking they are not minima. The variation that MR. JONES records may, I think, be fairly neglected in the face of the result of these experiments.

It has been asked why I did not make the snake bite the animals, instead of injecting poison.

Any one who has spent a morning in endeavouring to make a snake strike a single animal will know how dangerous and unsatisfactory such a course is. Apart from the

questions of time and trouble, there is always the uncertainty,

- (1) Whether the snake has really bitten.
- (2) Whether poison has been injected, for the gland may be empty or the strike may not have been a well timed one; and
- (3) Whether in any series of experiments the same amount of poison has been injected in each.

For reliable comparative experiments it is necessary—

Firstly—That one should know

- (a) that poison has been injected; and
- (b) that the same amount has been injected in each.

Secondly—That in each case the poison be similarly injected into equally absorbent parts, equally far from the heart.

Thirdly—that the minimum fatal dose of snake poison be ascertained and given in order that the antidote may have the fullest time and opportunity for any action it may possess.

A point of great value in experiments on animals with a syringe is that we thus avoid the great and error-bringing element of fright and fear of death which operates so strongly on a snake-bitten man.

Having settled the minimum fatal dose of cobra poison and the rapidly fatal dose for each class of animals, I next proceeded to ascertain the full physiological dose of B. P., liquor strychnia solution hypodermically given that could be injected into each class of animals, short of fatal effects.

These preliminaries settled, antidotal experiments were then undertaken. Every device was resorted to in order that the strychnine might have the fullest opportunity of exhibiting its vaunted powers.

That this was done you will see by reference to the table of experiments. In some cases the full physiological dose of strychnine was given as soon as cobra poisoning manifested its symptoms, in others the action of the snake virus was anticipated, in others small sub-physiological doses were repeated till full physiological effects were reached, while in yet others, poisonous doses of liquor strychnia were administered.

I regret to record that in no case did strychnia, however administered save life. In the whole 33 antidotal experiments, I have not one single case of recovery to tell of.

You will find in a tabular form a comparison of the relative duration of life in the various animals with and without strychnine. In the first eight cases the difference is practically negligible, in the next six it is strongly against the antidote, while in the last two there is no apparent difference.

I am far from insisting on the mathematical accuracy of these figures. Mr. Jones' report shows that the amount of poison in the drop varied in some cases, though in by far the greater number of cases it was $\frac{1}{4}$ gr. of dry poison. It is, however, more than probable that these variations did not favor either the control or the antidotal experiments taken as a whole.

Much must also be allowed for the individual idiosyncrasy of any particular animal, as experience often showed me, and yet allowing for all this, I think that one plain lesson is to be learnt, viz., that given an animal with a

poisonous dose of cobra poison, the substantial injection of strychnine often hastened death very markedly, while it never could be said to materially retard it.

It would seem that death may be hastened by the antidote in two ways:—

- (1) By increasing the force and frequency of the circulation and thus aiding the diffusion of the virus.
- (2) By the exhausting reaction which strychnine undoubtedly produces on the nervous centres.

Some of you were witnesses of the experiments, and I would feel obliged if you would state your opinions on these moot points which undoubtedly are of very considerable interest.

Strychnine at the bar of these experiments has failed to prove its case as a savior of life, but I go a step further and impeach it on the threshold of its claim to any antidotal power whatever.

I believe that the antidotal action said to exist between strychnine and cobra poison is a delusion and a myth.

Before proceeding to the hard region of fact, allow me to deal with Dr. MULLER'S contention on theoretical grounds.

That gentleman in his letter, dated Melbourne, 28th June 1890, to the Chief Secretary of Victoria, states:—“That snake poison is a specific nerve poison, depressing, and in fatal cases suspending, the functions of the motor and vasomotor nerve centres, and that this action is purely dynamic—it follows as a matter of necessity that if snake poison depresses the functions of the above named centres, the successful antidote must be a remedy that stimulates the centres to increased functional activity. This remedy is strychnine.”

Now if you have once proved the statement that strychnine and cobra poison respectively stimulate and depress the identical same centres, you may confidently anticipate that they will exert on each other an antidotal physiological action, but is this the case?

Strychnine I take it is a comparatively simple substance and its action can be the more easily estimated.

Cobra poison, on the other hand, is on a different footing entirely. Little as we know of it, we have already grounds for believing that it consists of at least two poisonous substances, one of which acts in such a way as to excite the motor portion of the nervous system and produce convulsions, while the other depresses the nervous system. Either of these separately is fatal. For all we know, and this opinion is held by able chemists, the poison possibly consists not of two but of many poisonous substances.

Turn now from chemical composition to the symptoms of the two poisons. Are they the exact complements the one of the other?

Time does not allow the thorough dealing that this subject demands, but I think that anyone who gives the matter a careful thought will admit that while the strychnine avowedly acts chiefly, if not entirely, on the motor centres of the cord, cobra poison shows the clearest evidence that at a very early stage it affects the higher cerebral centres, and probably the cerebellum. How else can we account for the drowsiness, giddiness and other allied symptoms?

Now, let us leave the airy region of theory for the more solid ground of observed fact, and ask ourselves the question. In actual reality do we find that strychnine shows itself in a modified form in a cobra-poisoned animal, or that cobra poison modifies its power before strychnine?

Set the strychnine control experiments side by side with the antidotal experiments, and you will observe the following facts:—

1st.—That symptoms of strychnine poisoning manifest themselves as early after the injection of strychnine in the one case as in the other.

2nd.—That in the early stages the convulsions of strychnine are as violent in one case as in the other.

3rd.—That in later stages animals die from cobra poison with typical symptoms, and yet the least touch evokes an undoubted strychnine tremor in the animal up to within a minute of death. An intermediate stage occurs in which the victim starts on the least touch or sound, but has not the *vis* to respond with a convulsion.

4th.—That under the influence of a poisonous dose of strychnine the animal dies as surely when fully under the influence of cobra poison, as it does when no such poison has been given. See experiments 93, 94, 95, 96, 97, and 98.

A very noteworthy point is illustrated by several experiments in which though the animal was so deeply under cobra poison that its exhausted nervous system could not produce a spasm, yet a fatal dose of strychnine precipitated the inevitable end.

This to my mind is a very different thing from physiological antagonism or antidotal action. It is not that the two poisons counteract each other in any beneficial sense, but that the cobra poison has so exhausted and depressed the nervous system, that the motor cells and muscle fibres can no longer respond to the strychnine stimulus with their accustomed violence, though that stimulus is amply sufficient to kill the exhausted animal.

5th.—That in some cases, *e. g.*, 11, 29, and 51, strychnine administered in physiological doses seemed actually to determine at once the impending fatal issue.

6th.—That in an animal poisoned with cobra virus, strychnine may produce a temporary stimulation and so may give rise to a fallacious appearance of improvement. I have watched this sign with hope on several occasions, but alas! those hopes have ever been doomed to disappointment.

Cobra poison 'bides its time,' like the knight of old, but like him too, when the time comes to strike, when in fact the virus would have killed in the absence of any counterstemp, it claims its victim as surely as fate. Strychnisation then passes into cobra asthenia, and do what you will with your drug, the curtain drops. The action of the poison forcibly reminds one of those little lines—

The mills of God grind slowly
But they grind exceeding small,
They may seem to pass us over,
In the end they grind us all.

I now turn to the second division of the subject before us, *viz.*, the records of experiment on man. It will be well to premise this part of our subject by a short description of the symptoms of cobra, krait and daboia

poisoning as observed by men for whose evidence we owe and all have the profoundest respect.

My object in so doing is to enable us to distinguish the true symptoms of snake poisoning in the cases before us from the mass of symptoms which are constantly and erroneously attributed to snake-poisoning.

Shortly then we may say that the signs and symptoms of cobra poisoning are as follows:—

Locally, stinging, burning pain; wound may become swollen, red and painful on pressure. An interval now occurs ranging in observed cases from 15 minutes up to 4 hours, the average probably 1 hour. Exceptionally symptoms may begin at once. First constitutional symptom a feeling of intoxication.

Then, drooping of eyelids, loss of power in legs, inability to stand. Later loss of power of speech, paralysis of tongue and larynx, falling of lower jaw, profuse salivation, nausea, retching and vomiting. Still later general spread of paralysis, suffocation by saliva threatens, muscular twitchings, respiration slow and shallow, consciousness retained in some cases, lost in others. Finally respiration ceases. Heart continues to beat.

For the above details I am indebted to WALL's Indian Snake Poisons, pp. 10—14. From the same author we learn the following details about other snakes;—

Daboia Russellii.—Local signs and pain in wound much more marked in bites by *Daboia* than in cobra bites, and there is a large amount of blood effused. Otherwise the two wounds are alike. In the constitutional symptoms of *Daboia* poisoning we note certain points differentiating it from cobra poisoning—

1st.—Convulsions are violent and constant at an early stage, but do not necessarily prove fatal. They are quite unlike the convulsions possibly of dyspnoeal origin which usher in death in cobra-bite.

Respiration is at first hastened, and does not so soon become slow and shallow as it does under cobra poison influence. It is very irregular in characters. Pupils widely dilated by the *Daboia* virus. Salivation far from common. Bloody discharges, and albuminuria are the rule.

After the nerve symptoms pass off a period of blood poisoning ensues which may last for days and very often eventually proves fatal. Hæmorrhage and hæmorrhoids attend this period.

In *Bungarus* bite, death takes place in one of two ways. Either at once by symptoms indistinguishable from cobra, except by the fact that the interval between the bite and the incidence of symptoms is here longer than in cobra-bite or later after an incubation period of 26 days by symptoms of blood poisoning.

The bite of *Echis carinata* is said to resemble that of *Daboia* but to be less deadly.

Having in this way cleared the ground, I would ask you to turn to the analysis of the recorded cases, which I have made, and copies of which are handed round to you all.

I would divide these cases primarily into two sets:—

(a). Those in which the patient was undoubtedly bitten by a poisonous snake this being proved (1) by his death with typical symptoms, or (2) by the snake being caught and identified by a trustworthy and competent authority.

(b). Those in which the patient recovered and the snake was not identified.

I shall deal with these classes in order, beginning with class A.

Out of a total of 42 recorded cases, we find a fatal result in 7, viz., in cases 1, 2, 3, and 7, 8, 9, and 10, nor can the antidotal drug be said to have been spared in any of these cases, not even in case 2 in my opinion. Very telling is Hospital Assistant MISRA's observant remark, that he found strychnine a failure in those cases in which speech was affected. This paralytic failure of speech is a well-known symptom of snake-poisoning and points to the fact that these fatal cases, and they only, were *Thanatophidial*, while the rest were spurious. Further it is to be remembered that fatal cases may very likely have escaped publication, as human nature shrinks from recording its failures.

Now let me turn to the cases in which the poisonous snake was caught.

I think that with the correspondence in the *I. M. Gazette* before us, not one of us will hesitate to exclude DR. BANERJI's cases from this list.

I may further add that DR. BANERJI very kindly sent me a consignment of snakes.

Of these he labelled two specimens as *Daboia Russellii*, one *Daboia elegans* and one *Daboia*—(something, which I can't read).

In the bottles with his own labels there is difficulty in ascertaining that they are every one typical specimens of *Echis carinata*, a much less virulent snake.

Another snake he labelled as *Bungarus coeruleus*. This diagnosis seems incorrect. The snake is 4 ft. 9 ins. long and, as far as the color can be distinguished (the specimen is decomposing), it is banded some dark color and yellow. It is probably *B. fasciatus*.

Another snake was labelled *Ophiophagus elaps*. It is merely a dark cobra.

Two specimens of the harmless tree snake, *Psammophis bituin*, are labelled *Callophis Pentalineatus* and *Callophis Graillii* respectively.

The *callophis* is a very deadly snake allied to the krait. I may say that DR. HENDERSON and MR. THURSTON have confirmed in every respect my opinion as to the nature of these snakes. I thank them both for the trouble they have taken.

Nor can I include No. 28, Assistant Surgeon FITZPATRICK's case, as the diagnosis there avowedly rests on native opinion, than which nothing can be more fallacious.

I recently had a good specimen of *Dendrophis Picotus* sent me by an educated and very intelligent native pupil, who assured me that the snake was believed to be more deadly than the cobra.

With DR. GIFFARD's able assistance I experimented with this snake on guinea-pigs which are very sensitive to snake poison. The snake seized and shook the little animals, making them cry loudly, but with entirely negative results.

Case 27 is recorded by one well known as a careful and trustworthy observer, Surgeon-Lieutenant-Colonel OSWALD BAKER, but that officer particularly calls attention to the

absence of symptoms, and in no way ascribes the recovery to the very small dose of strychnine ($\frac{1}{10}$ gr.) that he gave.

Case 30 by Surgeon-Major THOMAS cannot be relied on, as that officer acknowledges to having left the treatment in the hand of his Hospital Assistant after himself giving two injections. The amount of strychnine injected also seems very uncertain.

Case 31 is an interesting contribution to snake poison literature. It is in every respect carefully noted and recorded. The animal was *sans doute* a cobra, but the prompt and efficient local treatment rapidly adopted is in itself probably sufficient and accounts for the cure.

Surgeon-Major EVANS met with a similar case in his own practice in which early local treatment saved an undoubted case of cobra-bite, and possibly under the same head is to be included DR. HENRI's recent case.

In case 31 not one symptom of cobra poison is recorded if we exclude drowsiness, and, with characteristic fairness and openness, the recorders note that they nearly lost their patient from strychnine poisoning, which indeed they nearly did.

As to the drowsiness, I have noted in strychnine control experiments on animals, that, after the symptoms of strychnisation have passed off, drowsiness invariably and very naturally ensues.

To this point DR. GIFFARD and others of you who saw my experiments can, I know, speak.

Case 32 very courteously contributed in a private letter by Surgeon-Lieutenant-Colonel WALLER-BARROW is too scanty to found much of an argument on. The snake was nipped and probably quite unable to strike efficiently.

In any case no symptoms of snake poison are recorded.

Lastly we have a recent contribution in Case 42. Here the animal was a young cobra only 16 inches long, and like all young cobras very vicious withal. Strychnine was freely given in three large doses without any avail. Indeed we learn that the patient got worse and worse. After the fourth injection, and $4\frac{1}{2}$ hours after the bite, the patient began to mend and in another $2\frac{1}{2}$ hours was much better.

The only note of immediate improvement recorded is that muscular spasms commenced. My experience from experiments prevents me from considering this *ipse facto* a true sign of improvement, and I fail to be convinced, as the case now stands, that the improvement was more than *post hoc*. At the most, it may be claimed that strychnine acted like any other cardiac and respiratory stimulant would have done, but that there was any specific antidotal action I cannot admit.

It is however a valuable addition to our knowledge and would have been much more so had the symptoms been more carefully noted in those last $2\frac{1}{2}$ hours.

Pregnant with meaning in connection with this case, and with case 25 are DR. WALL's words which I extract from p. 94 of his valuable book on cobra poisoning. He says: "If the victim does not succumb soon, a complete recovery is to be anticipated."

Let us now turn to the second class or class B in which the snake was not caught and the patient recovered.

These cases can be divided into two classes :—

- (1) Those shewing signs of snake poisoning.
- (2) Those shewing no such sign.

For convenience sake we will dispose of the second division first.

Case 4 reads to me like a typical case of fright. Surgeon Captain GIFFARD relates the history of a man brought under his care in a state of profound collapse, under the impression that he (the patient) was bitten by a snake. Brandy and the assurance that a scorpion was the offender wrought a complete cure. How much more violent and effectual would have been the recovery had strychnia been substituted for brandy!

Cases 5, 6, 11, 12, 13, 14, 15, 16, are too scantily reported to be of any value in evidence.

Cases 17—21 present no marked symptom of snake poisoning or at least none such are recorded if we exclude three cases in which 'drowsiness and giddiness' are mentioned. I think we can hardly put much stress on these symptoms alone. The recoveries too are too rapid even for the most sanguine strychnia advocates in this country, the longest recorded case being cured in three hours. This taken with the smallness of the strychnine dose used, the scantiness of the clinical notes and the absence of identification of the snakes will lead most critics to reject these cases as valid evidence.

Case 22 had a large assortment of treatment with a little strychnia thrown in, but his symptoms are amply covered by the supposition that he was deathly frightened.

Case 24 presented no symptom that fear will not account for. Only $\frac{1}{2}$ gr. was given and recovery was attained in two hours.

Case 25 too seems to have been merely a case of fright, no symptoms of snake bite presenting themselves.

Case 28 powerfully suggests hysteria. Only 15 grs. of strychnia was given. The patient was a female *et. 35*.

Case 29.—The evidence is scanty as to (1) the nature of snake and (2) presence of snake poisoning.

Cases 33—38 have already been dealt with. I fear we can lay little stress upon them. The same uncertainty must necessarily surround all cases by the same writer.

Cases 39, 40 and 41 must fall in for their share of suspicion.

Case 39 reads to me like an intoxicated man who injured his foot or else received a harmless bite on it.

Cases 40 and 41 differ strangely from the experience derived from experiment, and from one case which was probably viper bite recorded by WALL, convulsions and typical hæmorrhage are conspicuous by their absence, as is also the intense local pain of viper bite.

Hospital Assistant MISRA's three cases recorded in the *Indian Medical Record*, 12th October 1894, are of no value. The snakes were not caught, the notes are scanty, and the symptoms doubtful.

A few cases remain in which the history of the case suggest thanatophidial origin.

Case 23 reads like a slight case of snake-bite. The fact that seven hours elapsed before it came under treatment is suggestive of the idea that the dose was not a severe

one. In the recurrence of the symptom on the third and fourth day, it would seem that a neurotic element played a part.

Case 25 was also probably a slight one of snake poisoning. The absence of subcutaneous infiltration warns us that at least the dose was not large, even if the bite was thanatophidial. Dr. VAGHAN's idea that cobra poison does not cause such injection is directly opposed to the experience of WALL, and in this particular I can certainly bear that observer out, having constantly noted subcutaneous infiltration in animals even with diluted cobra poison. Dr. VAGHAN noted that he administered 3 grs. in 50 minutes without improvement. After another 1 gr. gradual improvement commenced. Was this *post hoc* or *propter hoc*? At least here we see none of that sudden disappearance of all symptoms over which Dr. MUELLER is so jubilant in his cases.

Case 42 is ably discussed. The fangs of the snake seem not to have penetrated, and it is doubtful how far the symptoms were due to cobra-bite. Dr. SARGENT notes that hysteria and fright were strong elements in the case, and he does not hesitate to shew us how nearly he lost his patient by over-strychnisation. It is to be regretted that all men are not equally honest.

Finally it is noteworthy that Dr. SARGENT does not credit strychnine with saving the case, though he thinks it hastened recovery. Very probably brandy or any other stimulant would have done the same.

Case 44 seems to have recovered from cobra poison and strychnine. In $1\frac{1}{2}$ hour $\frac{3}{4}$ gr. of strychnine was given, and the patient was then left to the mercies of his friends. During the next six hours, he grew worse and worse, though the jerking of the limbs showed he was under the influence of strychnine, for at least four hours of that time. Eventually nature prevailed, the two poisons were excreted and the man rallied.

I have endeavoured fairly but critically to review these cases. My aim has not been, and is not, to persuade any one of you to adopt the view to which I myself have been driven, but I hope rather that I may have been able to place facts before you and to allow you to judge, each one for yourselves.

For my part before I can accept the conclusions, Dr. MUELLER would force upon us, I must know of at least one recorded case, (1) in which a well grown poisonous snake struck a man, woman or child, (2) in which that snake was identified by a reliable authority and proved to possess fangs and a poison sac, or in which in another case, a fatal result followed a bite by this same snake, (3) in which symptoms of undoubted snake poisoning appeared and were definitely removed by the administration of strychnine.

I cannot accept cases in which strychnine was given and after an indefinite period 'the patient got better.'

No such cases are forthcoming, and to my mind while experiments on animals condemn, experiments on man do not definitely and distinctly support Dr. MUELLER's treatment.

I can only quote the words of one who rendered me valuable and valued assistance while I re-echo Dr. DYMORT's sentiments. "If I am bitten by a snake, I

will at least not superadd to my suffering the agonies of strychnisation. Let me die in peace."

It may be that words have fallen from me to-day which seem unkind to fellow-workers in this great and important field. If so, I can assure them that my intention was not to wound, but the interests at stake are such that I have felt it incumbent upon me to be 'faithful to truth at all costs.'

If to any I seem an idol-breaker, I would ask them to believe that in breaking their idol, I have broken my own, for I set out on this quest in the hope and belief that at least there was a strong nucleus of truth in the stories that garlanded the strychnia treatment of snake-bite. I have been rudely undeceived, but what profit is it to any one of us to nurse a jackass in the delusion that it is a form of beauty. It is better to awake from such a dream at once.

In conclusion I must thank the many who have accorded me valuable and willing help.

My best thanks are due to the Surgeon-General and the many officers of the I. M. S. and others who at the sacrifice of valuable time, came and witnessed the experiments on this subject. By so doing they have set on this work the stamp of genuineness which, had it been less public, many might have held it to lack.

I would thank Surgeon-Lieutenant-Colonel ALLISON for much courteous help with the proof sheets and other details. Surgeon-Captain THOMSON for so readily and valuably assisting me with all the information in his power. Mr. JONES, Professor of Physics at the Presidency College, for very kindly weighing specimens of poison for me. Mr. THURSTON and Dr. HENDERSON for ready assistance in the identification of snakes, and Mr. SAMBU SIVA my assistant professor and Mr. GOVINDAN my demonstrator for much willing and able help. Lastly, but far from least, I would tender my very best thanks to two officers of the I. M. S. who stinting neither time, labor nor pains, gave me almost throughout my work their constant and most practical help. By their clear headed advice and ever useful suggestions they contributed in no small measure to any success my work may have attained. I need not say that I refer to Surgeon-Major DYMOTT and Surgeon-Captain GIFFARD.

The President made the following remarks :—

"We have all heard with great interest the valuable paper by Surgeon-Lieutenant ELLIOT, a careful record of successfully made experiments, some of which I with others of you have had the opportunity of seeing carried out. I am sure we, who saw these experiments, will all agree that they could not have been more thoroughly performed or in a more scientific spirit than Dr. ELLIOT shewed. These experiments I consider clearly shew that the antidotal power of strychnia in cobra poisoning, as claimed for it by Dr. MUELLEN, does not exist; and, moreover, that in using it we are dealing with a dangerous remedy which itself is very likely to prove fatal, if not administered with the greatest caution and under the closest personal observation. The Government of India, not being satisfied that the result of the experiments submitted to it were conclusive enough, have ordered further trials and further reports. I consider it would be most desirable that these investigations of

Dr. ELLIOT should be given as wide a circulation as possible for the information of those medical officers who may have the opportunity of carrying out such further investigations in order to show them how necessary it is that such experiments should be carried out with great care and in a true scientific spirit."

Brigade Surgeon-Lieutenant-Colonel W. PAICE said :—

"As I was one of those who enjoyed the privilege of witnessing many of the interesting experiments upon which the valuable paper we have just heard read has been founded, I feel that it is my duty to say a few words.

First of all, I wish to thank Surgeon-Lieutenant ELLIOT for his kindness in having asked me to attend and next to bear witness to the care, accuracy and skill with which the numerous experiments were carried out and the results recorded. I was present on three days, and at three different sets of experiments. I watched them carefully and I am now fully satisfied that not only is strychnine not an antidote to cobra poison, but that, on the contrary, it actually hastens the end, and it does that in a most unpleasant way for the patient. If I were unfortunate enough to be bitten by a cobra, I would most certainly not let any one inject me with strychnine; neither would I permit any cobra poisoned patient of mine to be so tormented. I certainly think that these experiments not only justify but necessitate, in the interests of humanity, that Government should withdraw its order sanctioning experiments with strychnine on cobra poisoned human beings. Dr. VINCENT RICHARDS, in his valuable little book on 'Landmarks in Snake Poisoning' gives some very simple practical directions for the treatment of these cases which might with advantage be made more widely known. The intelligent policeman or village official would be much less likely to do harm with a piece of India rubber tubing than with a hypodermic syringe and a solution of strychnine. I may state that when serving in the Nellore District, a very "snakey" place, I used to go about with a piece of India-rubber tubing in my pocket, but though I served there nearly four years, I never got an opportunity of using it.

"One point in the experiments that interested me greatly was the well marked "currant jelly" condition of the tissues surrounding the cobra poison injection. It was so well marked that no one could mistake it for a moment. VINCENT RICHARDS lays great stress upon this point in the diagnosis of a poisoned bite from a non-poisonous one, and also upon the removal of all this "currant jelly" tissue in the treatment of the former, yet, as well as I remember, this is a point that is seldom touched upon in either a cured or fatal case. It ought certainly to be widely known.

"As a matter of personal faith, I believe that the deaths from snake-bite are very much exaggerated, and that the figures put down under this head include many murders of sorts. I have lived in India and Burma for over twenty-three years, and during that time have served all over the country from Palamcottah in the South to Nowgong, Central Provinces, in the North, and from Mangalore in the West to Toungoo, Burma, in the East, and in that time have seen only four cases of snake-bite, not one of which was fatal. Two of them were brought in

an apparently unconscious state; but when I found that this had come on immediately they had been bitten I did not put it down to snake poison. They recovered without strychnine. You may say that cobra bite is so rapidly fatal, there is seldom time to bring the patient to the medical officer for treatment. Granted; but it seems to me that if deaths from snake-bite were as common as they are said to be, I ought to have seen a corpse in my varied and fairly long service.

I noticed that Dr. ELLIOT spoke of injecting into the abdomen in preference to the thigh. We know he means the subcutaneous tissues of these parts, but it might be as well to say so."

Surgeon-Lieutenant-Colonel BROWN said:—

"Having had the privilege of witnessing the experiments on monkeys made by Surgeon-Lieutenant ELLIOT, I would like to state that I fully agree in the main with the conclusions that he has drawn from the experiments. To my mind they are quite conclusive as to the utter uselessness of strychnine as an antidote to cobra-poisoning in animals. There could be no doubt whatever that instead of in any way alleviating the symptoms or delaying the approach of death, strychnine made the animal suffer a great deal more than it otherwise would, if the cobra-poison had been allowed to act *per se*, and further strychnine undoubtedly hastened the onset of death.

In no way could strychnine be said to shew any power as an antidote, and no matter how the experiments were devised, the result was always the same; namely, a painful and more speedy death when strychnine was used than when it was not. Dr. ELLIOT has said that Surgeon-Major DYMOTT expressed his decision not to be injected with strychnine should he ever be bitten by a venomous snake, and I certainly am of the same opinion, and should I ever have the misfortune to suffer from snake-bite, I shall certainly not allow any one to inject strychnine into me—as long, at any rate, as I retain consciousness. Before sitting down, I shall like to add that the experiments were thoroughly conducted in a thoroughly scientific spirit, and Dr. ELLIOT was always anxious that every medical man who cared to do so, should witness as many of the experiments as possible. Further, I think that means should be taken to publish the admirable paper that we have just heard read, so that it may reach a wider circle than our own branch, especially as the matter is still under reference by the Government of India—and also because, as far as I know, no such valuable series of experiments has been undertaken either in India or elsewhere as the one, the delivery of the record of which, we have just had the privilege of listening to."

Surgeon-Lieutenant-Colonel H. ALLISON said:—

"I also had the privilege of witnessing some of the experiments carried out by Surgeon-Lieutenant ELLIOT and desire to add my testimony to the great care with which the experiments were conducted. I fully agree with the conclusions drawn from them, that strychnine is not an antidote to cobra poison."

Surgeon-Captain GIFFARD said:—

"Having been privileged to witness not only some but nearly the whole of Dr. ELLIOT's experiments, of the many points that have struck me, I consider the greatest

and the most significant to be, that in not one single instance has recovery taken place in any animal, with or without strychnine, into which had been injected one drop of cobra poison. Had there been a single doubtful case, I should have considered it a call for more experiments, but as matters now stand, the 'case' for strychnine must be considered 'closed' at least as far as animals are concerned. Of the remaining points I am so convinced of the danger of the use of strychnine; I say ~~was~~ advisedly, for of the danger of its abuse there can be no doubt, that I consider that not only would that drug fail to cure cases of poisoning by cobra poison in which the dose was such as to ensure death, but also I greatly fear that it may be found to cause death in those cases in which the dose was such that, if no treatment was adopted, recovery would or might ensue. I take it, that the profound shock and subsequent nervous depression and drowsiness always seen after marked strychninisation would militate very considerably against the recovery of those cases that might be considered, as it were, as the border line between recovery and death. I consider strychnine in animals to be not only "no antidote," but also a no problematic danger to the slightly poisoned case. I would also remind the meeting that Dr. ELLIOT's method of giving strychnine was no hard and fast rule, but with every endeavour to give the drug fair play, it was given in single and in multiple, in small and in large doses. Some of the members now present will remember that having been asked by Dr. ELLIOT towards the end of the experiments whether any one still had a lingering hope that some special manipulation of the dosage of strychnine might perhaps save one case, he then carried out the suggestions made and as before stated with the monotonously invariable result "death."

The following letter has been received from Surgeon-Major DYMOTT, who was present at most of the experiments:—

"I am sorry I was unable to be present when you read your paper. I saw so many of your experiments that it would be a failure of duty if I did not bear witness to the care and persistency with which you conducted your operations.

The results seemed to be so conclusive that before you had finished one-fourth of your experiments, I really thought that the question under consideration was sufficiently settled. In no case, where strychnine was injected after cobra poison, was there the slightest evidence that the strychnine in any way prolonged life.

Though you have undoubtedly proved that strychnine is not an antidote to cobra poison, the evidence in those cases where human beings have been bitten by snakes and treated with strychnine, does not so clearly shew this. There must be some reason for the apparent discrepancies in the results, and, on reading your paper, I at once noticed an important difference in the two classes of cases. Your experiments on animals were all made with a syringe, in order, as you say, to avoid the great and error-bringing element of fright and fear of death. In the cases quoted, where human beings were bitten, we may reasonably suppose that there existed this element of fright and fear, and, though strychnine may not be in the slightest degree an antidote to cobra poison, it may, and probably does, help to remove the condition produced by fright and fear.

There are, however, other equally efficient and far less dangerous remedies.

Your experiments have furnished still another instance of the benefit to mankind resulting from vivisection on the lower animals."

Surgeon-Lieut. R. H. ELLIOT very kindly sent me this article for publication. It was read before the Medical Branch of the British Medical Association.

FILARIAL DISEASE.*

BY SURGEON-MAJOR J. MITTLAND, M.D.

Elephantiasis and other diseases caused by the *Filaria Bancrofti* are so widely prevalent in certain parts of India, and there is still so much to be learnt regarding them, that the subject seems to be an especially fitting one for discussion at this Congress. Filariæ disease appears to be prevalent along the whole coast line of India, and in some places, such as Shertullay in Travancore and Streehareekota in the Nellore District, a large proportion of the inhabitants are said to be affected. Yet the disorder is often so insidious in its approach that cases are frequently overlooked by medical men, and there is strong reason for believing that the disease is much more common than is generally supposed.

It is exceedingly important that we should be able to recognise the disease in its early stages, as much may then be done to mitigate it, if suitable measures are adopted. Moreover, the medical man in India is so frequently called upon to examine candidates for employment in the service of the State, or recruits for the Army, or applicants for life insurance, that he should always be on the alert to detect the early manifestations of these disorders.

DR. MANSON has written so recently and so exhaustively on this topic, in DAVIDSON'S "Hygiene and Diseases of Warm Climates," that I have no intention of going over the general facts which he has so well described. All physicians who have had much experience of filarial disease will probably agree with him in most of his conclusions, and more especially so in his opinion, that the so-called Elephantiasis Arabum is merely one of the many manifestations of this protean disorder.

My chief object, however, is not to discuss any of the matters treated of so fully in the above-mentioned work, but to describe certain new facts which have come to light within the past eighteen months, and to discuss their bearing upon the pathology and treatment of certain forms of filarial disease.

Before proceeding further, it will be well to give a brief outline of certain cases to which frequent allusions will be made, and upon the facts of which most of the following observations are based.

No. I.—This was the case of a young Eurasian, who, although he had embryo filariæ in his blood, did not present any other evidences of disease. One day he received a blow upon his arm and this was followed in a week's time by an attack of lymphangitis at the injured part. The inflammation quickly subsided under treatment, but left an induration of the part affected. The lump of thickened tissue was excised and on dissection was found to contain a number of mature filariæ.

No. II.—This was a somewhat similar case to the last. A Mahomedan lad, who had filariæ in his blood, and who was suffering from an attack of acute synovitis of the knee joint, said to be of traumatic origin, suddenly developed lymphangitis of the arm. The inflammation soon subsided, but left two thickened masses which were subsequently excised and found to contain a number of mature filariæ.

No. III.—This was a Eurasian lad who had enlarged glands in the femoral region on both sides, and who also had filariæ in his blood. He had suffered from a few attacks of mild fever, but was otherwise in apparently good health. The mass of glands on one side was removed and on dissection was found to contain several mature filariæ. The operation was followed by complete disappearance of filariæ from the blood.

No. IV.—A Hindoo youth had enlarged and varicose glands in the femoral region on one side, and filariæ in his blood. He suffered from frequent and severe attacks of pain and fever. The glands were removed and the attacks of pain and fever ceased.

No. V.—A Eurasian lad with a swelling similar to that in the last case but with no filariæ in his blood. He also suffered from attacks of pain and fever. The glands were removed, but without benefit.

No. VI.—A similar case to the last. A Eurasian lad with varicose groin glands, but with no filariæ in his blood. He suffered from periodic attacks of pain and fever. The glands were removed but the result of the operation is not known.

Some of the filarial worms obtained from one of these cases were examined by DR. MANSON, and a description and illustrations of them were published in the *British Medical Journal* of the 21st April last. On comparing them with the description and drawings of the worms previously described by MAGALHAES, DR. MANSON was of opinion that these were specimens of the mature *filaria bancrofti*, but that MAGALHAES' filariæ are quite a new species.

Some of the cases which I have briefly narrated afford us new and interesting information regarding the habit of the filariæ and the manner in which these parasites dispose themselves in the lodging that they select for their residence. Surgeon-Lieutenant ELLIOT, who very kindly examined the mass of glands removed from the third case, says that "while dissecting a mass from one of the larger glands, a capsule seemed to have been burst and a much coiled elastic mass of worms sprung open with a watch-spring-like movement"—and further on he says "while dissecting one of the smaller glands, a membranous material, which apparently acted as a capsule, was torn across and a third worm discovered." His observations led him to conclude that the worms were in all probability encapsuled and they certainly were enclosed under pressure. In the tissues removed from the second case the parasites were contained in small cyst-like cavities about an eighth of an inch in diameter, and lined with what appeared to be an adventitious cyst wall formed of effused lymph. They were coiled up together in tangled masses and surrounded by pus. In the first case the worms were coiled up in a mass, but no cyst wall was noticed; allowance must, however, be made for the fact that the tissues had been macerated for some time previous to dissection, in a strong acid solution. One of the cysts contained two worms; a male and a female. Another cyst contained a solitary female. In the other instances the numbers contained in each separate cyst were not determined. Some of the worms were broken in the attempts to disentangle them, and hence it is not quite

* Being a paper read at the Indian Medical Congress and sent to the Record for publication.

certain what the total number, discovered was in the three cases; but twelve females and five males were counted.

In the first two cases the worms were either contained in lymphatic vessels or were in close relation to them, but in the third case they were situated in the interior of lymphatic glands. The latter is a fact not previously observed, and bears, as we shall see, an important relation to the pathology of certain forms of filarial disease, and more especially to their treatment. A consideration of these facts appears to warrant the following conclusions, *vis.*, (1) that the worms may be found not only in the lymphatic vessels, but also within the lymphatic glands; (2) that they lie coiled up in tangled masses which are enclosed, under pressure, within small cyst-like cavities; and (3) that each cavity may contain one or more worms.

Passing to a consideration of the lesions which result from the presence of the filariae, we find one or two interesting points for discussion. In case No. I there was a blow on the arm which probably killed the filariae, and an effort was then made by the tissues to throw off the offending bodies by setting up inflammation. In case No. II the parasites died and their dead bodies gave rise to inflammation and suppuration, but the cause of their death, in this case, was obscure. That certain diseases of the host have an influence upon the filariae is evidenced by the fact that periodicity in the appearance of the embryos in the blood is disturbed by the febrile condition. It is also not improbable that some drugs, such as quinine and mercury, have an effect upon them. It is not uncommon to find that the onset of elephantiasis has been coincident with an attack of syphilis, and indeed many of the old writers ascribed the disease to syphilis. May not the syphilitic virus, or some of the remedies used for its cure, cause the worm to abort, or even cause its death? In case No. III the natural assumption would be that the enlargement of the glands was caused by the parasites contained within them. It might be said on the other hand that the fact of the glands being enlarged on both sides of the body, pointed to the probability of an obstruction high up in the lymphatic system; the dilatation of the lymphatics in the groin being merely part of a general distension of the whole lymphatic system situated above the glands. If this were the case, however, we should have found that the lymph contained in the groin glands was chylous in character. This was not the case, nor were there any indications whatever of general dilatation of the lymphatics of the trunk. This point, as we shall presently see, has an important bearing upon the question of treatment. It seems reasonable, on the whole, to assume that the changes in the glands in this case were due to the parasites contained within them; the direct cause probably being plugging of the ducts by prematurely discharged ova.

Let us now pass to a consideration of the all important subject of treatment. Do the facts that have been brought to light by these and other cases afford us any indications as to treatment? Five years and a half ago, a young man, whose case (No. IV) has already been alluded to, came under my care, suffering from varicose glands of the groin, and on examining his blood filariae were found.

He suffered from frequent and severe attacks of pain and fever, so much so that he was unable to follow any occupation, and he begged for something to be done to afford him relief. In thinking over his case it struck me that the parasites might possibly be situated within the diseased glands themselves, and that, if this were the case, removal of the glands might afford the patient relief from further trouble. When this suggestion was made to the patient he readily consented to an operation being undertaken. The mass of diseased glands was accordingly removed by operation and the patient got well. Five months afterwards a swelling appeared in the opposite groin, but there were no more attacks of fever and pain and he was, and still is, able to carry on an active life in the mercantile profession. The mass of glands that was removed was unfortunately lost, and no opportunity obtained for examining them, so that it is impossible to say whether any parasites were present within them or not. The satisfactory result of the case however seemed to justify the hope that similar operations might be of benefit in other cases of filarial disease, and the recent discovery of filariae within the diseased lymphatic glands, in a case very similar to the above, appears to afford an additional justification of the operation.

Certain French surgeons, who have investigated the question, are opposed to this operation on the grounds that it is very liable to be followed by septicæmia. But such an objection can scarcely be considered a valid one in these days of antiseptic surgery.

In advocating operations for the removal of diseased lymphatic glands in cases of filarial disease, I would, of course, exclude all those cases in which the local lesions are manifestly merely a part of a widespread dilatation of the lymphatic system, due to an obstruction situated high up, in or near, the thoracic duct. MANSON'S experience lead him to believe that very many, or nearly all, cases of varicose groin glands belonged to this class, as evidenced by the fact that the fluid contained within them was chylous. Our experience in Madras is opposed to this. I have only seen one case in which there was a suspicion of the obstruction being seated at all high up, and no cases in which chyluria had ever occurred. Putting aside such cases as these, it seems to me that there are a considerable number of instances in which operative treatment promises to be of service in mitigating, if not in curing, the disease.

These cases may, for the sake of convenience, be divided into the three following classes:—*Firstly*, cases in which the lymphatic glands are enlarged and varicose and in which filariae are found in the blood, but where the diseased condition is not part of a widespread dilatation of the lymphatic system. When we meet with such a case and the patient suffers from frequent attacks of fever and pain, which seriously disable him, and render him unfit for any active occupation, I think we should recommend an operation. The experience furnished by the case already related shews that very great relief may result from removal of the diseased glands. Whether we should operate on cases in which similar lesions are present, but which are not attended by any suffering or inconvenience, is another question, and one that cannot be definitely settled until further experience has been gained.

The case alluded to as No. III may be considered an example of this class, and furnishes evidence in favor of operation. The patient had varicose glands in both groins and many filariæ in his blood, but he was not suffering from pain or inconvenience. Nevertheless, the presence of the tumours, and the knowledge of the disease, caused him great mental anxiety, and he was anxious to undergo any treatment, operative or otherwise, which offered a chance of getting rid of the parasites. On the day following the operation all filariæ disappeared from his blood, nor have any been seen since then, although a period of three months has elapsed. These facts favor the belief that all the parasites have been removed and that the patient has been delivered from all chances of future trouble. Too short a time has elapsed to enable us to say more than this, but the case appears to furnish strong evidence in favor of operation.

The second class of cases are those in which, although the glands are enlarged and varicose, yet there are no filariæ in the blood. Cases belonging to this class are not at all uncommon. During the past eighteen months I have operated upon three such cases, two of which have already been alluded to as Cases IV and V. The fact that there are no filariæ in the blood does not shew, as MANSON long ago pointed out, that the disease is not of filarial origin, but rather that that part of the lymphatic system, which is inhabited by the parasite, is shut off from all communication with the blood, by blocking of the passages. When such cases are accompanied by much suffering, an operation may afford relief. The probabilities are that the dilatation of the lymphatic channels is purely local, and the operation is not attended by any special danger. It is unfortunate that two out of the three cases alluded to have been lost sight of, and the result in those instances not known. In the third case, I regret to say, there has been no benefit whatever up to this time. The failure appears to be due to the operation not having been a sufficiently radical one. The femoral glands alone were removed, whereas the inguinal glands appear involved in the disease, for pain is now felt in the latter and they have become swollen. It is a question whether we ought not to recommend operation in all cases of this class, no matter whether there are attacks of pain or not. If, as we have grounds for believing, filariæ are present in the glands, there is always a possibility of some further development of the disease taking place, unless this be prevented by timely extirpation of the glands along with the parasites concealed within them.

The third class of cases are those in which, under ordinary circumstances, there are no indications of filarial infection, but in which, owing to causes that may or may not be evident, inflammation is suddenly developed in that part of the lymphatics that is inhabited by the parasite. Examples of such cases are those alluded to as Nos. VIII and II. Cases of this nature are not uncommon, and I have met with several others besides those related in this paper. It is probable that in many cases the worms are dead; still we have no certainty of this, and when the part affected is easily accessible, it is better to make an attempt to remove the parasite.

These are the three classes of cases in which it seems justifiable to hope that operative treatment may, in some instances, be a means not only of alleviating the disease, but possibly of curing it.

Before concluding this paper, I should like to draw attention to one or two points connected with the operation for removal of elephantiasis of the scrotum and penis. The difficulty of covering in the structures, laid bare during this operation, has led to the suggestion of a variety of procedures for effecting this object. At one time it was the practice to preserve portions of the scrotum, as flaps, to cover in the testicles, but the result of experience soon proved the uselessness of such attempts, and the light shed upon the pathology of the disease has served to demonstrate the cause of such failures. This procedure is fortunately unnecessary, because we can attain the same end by different means, and the testicles can be easily and effectively covered in by skin taken from the thigh. This is effected as follows:—The scrotum having been completely removed, the skin on either side of the wound, that is to say, the skin of the thigh, is dissected up from the subcutaneous tissue for a distance of two inches opposite the centre of the wound, and to a lesser extent above and below this point. The patient's thighs are then approximated and the two portions of skin easily united with one another in the middle line, completely closing in the testicles and embracing the root of the penis.

Various methods of covering the penis with flaps of healthy skin have been tried, but none have proved satisfactory. I have for some time practised THIERSON'S method of skin-grafting, and strongly recommend this procedure as one which expedites the healing of the wound, and to a great extent prevents that contraction of the penis, which always results, unless some such measure is adopted. The procedure consists in the application of a number of skin grafts, at the time of the operation, and is carried out as follows: Several long strips are cut from the anterior surface of the thigh, the skin of which has been as thoroughly purified as possible. The section of the skin should be made deep enough to include the tops of the papillæ, but no deeper; and after the graft has been stripped off, a white surface should be left, dotted over with minute drops of blood. The strips of skin are next divided into portions about half an inch square and laid smoothly on the surface of the penis, so as to cover the whole organ, which is then covered with a dressing of boric acid ointment, fastened so securely as to avoid any chance of its slipping. If the grafts are cut of a larger size than those described they are more apt to become displaced than if smaller ones are used.

PERSISTENT AMBLYOPIA DUE TO QUININE.

A man thirty-five years of age recently came under the notice of M. DEBRIÈRES. The patient complained that for the past three months all objects perceived appeared to him to be covered with down, and that, in addition, he was colour-blind. This visual trouble had come on one morning after the ingestion (on the previous evening) of four teaspoonfuls of sulphate of quinine, he being at the time under the influence of drink. As a rule, this quinic amblyopia disappears rapidly, but in this case the condition was persistent, probably owing to alcoholism.—*Querc.*

THE NEED OF A SANITARY SERVICE FOR INDIA.

By W. J. SIMPSON, M.D., M.R.C.P., D.P.H.

Health Officer of Calcutta.

INDIAN medical men have always taken an interest in the sanitation of those parts of India in which they have been stationed and have from time to time pressed on the attention of the Government the desirability of introducing measures for the removal of unhealthy conditions. These representations have invariably received careful and courteous consideration, and have been attended with considerable success, for to them are due, *firstly*, the vast improvement in the health of the army, which has taken place; *secondly*, the appointment of sanitary commissioners with its consequent recording of the health conditions of the civil population, the collection of statistics, the recent sanitary progress effected in large towns, notably in water-supply, the spread of vaccination and the management of large fairs; and, *thirdly*, the appointment of central boards of health in each province, all of which may be justly claimed by the Indian Government as achievements of no small importance, and on which they may be warmly congratulated. Not then forgetful of the past and of the advances which have been made under great difficulties, we medical men shall, however, only be following our old traditions when we undertake to point out the great defects in the existing system of sanitation in India and the measures necessary for further progress. And this is the purpose of the present paper.

There is no necessity of marshalling an array of striking statistics to prove the insanitary condition of the more advanced parts of India. That has been done many times previously, and it will therefore suffice in passing, to merely bring to the recollection of the members of the Congress that in 1892, which is the year dealt with in the last report issued by the Sanitary Commissioner of India, there were in the European army 1,509 admissions and 376 deaths from enteric fever; and in the civil population out of over 7 millions deaths recorded more than $\frac{1}{2}$ million are ascribed to cholera and over $4\frac{1}{2}$ millions to fevers. These are remarkable figures, and reveal in their own way the unhealthy state of the country. But to come down to a still later period than that of the Sanitary Commissioner's report, two events which have happened during the present year furnish startling evidence of the unsafe condition of the country in regard to health matters. One is the calamity that befell the East Lancashire Regiment stationed at Lucknow, in July and August, in which, notwithstanding every effort on the part of the medical officers, out of a total strength of 778 men 138 were attacked with cholera, of whom 92 died; the other is the disastrous outbreak of cholera which occurred in August last in the Sir JAMES WATSON Hospital in Bombay, in which out of nearly 400 patients being treated in the hospital for *intestinal diseases* 84 were attacked with cholera, of whom 36 died. In the army and civil population alike then the defence against preventable disease is extremely weak and uncertain. There can be no doubt about the preventable nature of typhoid and cholera, and

this being so, the same question may be asked at the first Indian Medical Congress as that put by His Royal Highness the Prince of Wales in his presidential address to the Seventh International Congress of Hygiene and Demography, when referring to preventable diseases:—"If preventable, why not prevented?" For India the answer to this question is plain and clear. It is that as regards the civil population, which necessarily affects the army in its midst, there is no efficient sanitary service, whose duty it is to prevent preventable disease. Impressed though I have been for a long time with this fact, yet, prior to placing before the Congress my views relating to the need of a more efficient sanitary service for India and the basis on which that service should be established, I felt it incumbent on me to consult a number of the civil surgeons distributed over different parts of India and invite their opinions on the subject of municipal sanitation. I confined myself to municipal sanitation, for it seemed to me desirable to follow the lines of least resistance and endeavour to secure efficiency here before attempting seriously any advance in the direction of village sanitation. With that object in view, I addressed to the Civil Surgeons the following questions:—

- (1). As a Civil Surgeon, have you sanitary duties in the municipality? (b). In what do these duties consist? (c). Does the municipality place at your disposal a certain sum of money for this work?
- (2). Do you think the existing arrangements good or not, and why?
- (3). What organization for sanitary inspection and sanitary duties, *excluding vaccination*, exists in the municipality? (b). Is this organization under the Chairman of the municipality or directly under yourself?
- (4). If there is an organization, what modifications or improvements do you think desirable?
- (5). Apart from the Sanitary Commissioners and Deputy Sanitary Commissioners of the Province, do you think that a qualified local Sanitary Inspector or Sanitary Officer should be attached for sanitary work to the municipality?
- (6). Should this Sanitary Officer be under the Chairman of the municipality or under the Civil Surgeon?
- (7). Do you think that some of the sanitary duties could be combined with those of the present Assistant Surgeon, or should there be an additional qualified man paid by the municipality placed under the Civil Surgeon for that purpose?

Some 70 Civil Surgeons responded to my invitation, many of them supplementing the space I had allotted to each question by private letters entering more fully into the matter. All exhibited a keen interest in the subject, and my first duty on this occasion is to cordially thank those gentlemen for their great courtesy and assistance. A *résumé* of their opinions has been attached to this paper, and it is remarkable how unanimous these opinions are on the unsatisfactory state of the present arrangements, the powerlessness, as a rule, of the Civil Surgeon in sanitary matters, and the necessity for improvement. Equally unanimous are the opinions given regarding the undesirability of the Assistant Surgeon taking over any sanitary duties, *first*, because he appears to be a very hard worked official; and, *secondly*, because sanitary functions

* Being a paper read at the Indian Medical Congress and sent to the Record for publication.

devolving upon him would likely render him unpopular and disturb the confidence and esteem he is now held in by his patients. Instead of employing locally the Assistant Surgeon for superintending sanitary matters, most of my correspondents are in favor of a specially qualified man, some of them suggesting officers in the Subordinate Medical Department, such as Apothecaries, Civil Hospital Assistants and others. Among the suggestions is one, that in each province there should be a staff of Assistant Surgeons trained in hygiene and sanitation especially, graded and receiving the same pay as Assistant Surgeons in the medical branch, the higher graded men being employed by the larger municipalities; but Assistant Surgeons in the sanitary branch not to be interchangeable with those of the medical branch. These suggestions and others to be found in the summary of opinions in the appendix disclose the sympathetic interest with which the whole question of avoidable sickness and its prevention is considered by the Civil Surgeons.

From the information I have collected, it is evident that the power in sanitary matters lies wholly with the municipalities. Government in an undefined way expects the Civil Surgeon to be the adviser on sanitation to the municipalities in his district, but has invested him with no real authority or power to enforce his recommendations, or see that they are carried out, and unless he happens to be Chairman of the municipality as at Puri, a circumstance due mainly to special attention having been directed to the insanitary condition of this town, or unless the Chairman of the municipality happens to be a European who is ready to listen to the Civil Surgeon's advice, the system breaks down. As a member of the Board the Civil Surgeon may, by his personal influence, be able to get many improvements carried out, especially if they do not involve much expense. As a general rule, however, should a Civil Surgeon in the peculiar position he now occupies, make himself active in sanitary matters, his want of power is soon brought home to him by his advice being disregarded or by a polite note, stating that there are "no funds available." On the other hand, it not unfrequently happens that the Civil Surgeon's time is so occupied with his medical duties that it is quite impossible for him to devote his attention to sanitary matters.

The consequence of the delegation of power in sanitary matters to local authorities without introducing simultaneously an effective system of authoritative guidance and control, has not been sufficiently realised, nor has its paralyzing effect been sufficiently appreciated to rouse the Government to action. From a sanitary point of view, it is deplorable that the introduction of local self-government should have placed the sanitary administration of the country in such a position. In every great progressive measure introduced, much that is unexpected and unforeseen is almost certain to subsequently manifest itself and require after-adjustment. So it has happened with the scheme of local self-government for the more advanced parts of India. The defect which is the most patent and the most injurious is the total absence of any machinery to carry on local Government sanitation. The transfer of power and of duties relating to public health to local authorities, totally unacquainted with the

principles or practice of preventive medicine, and the omission to provide at the same time an efficient and strong local and central agency to guide and control these authorities, are the two important factors at work, bringing discredit on local self-government and impeding sanitary progress in this country as a whole.

The kind of agency and the necessity for it will be best shewn by a comparison of the sanitary service in England and that in India.

In England with a population of a little over 26 millions and an area of 58,310 square miles, there are over 1,500 medical officers of health for municipalities and sanitary areas, rural and urban. There are also 12 county medical officers of health and more are being gradually appointed. These, with the army of Sanitary Inspectors under them, constitute the local agency of the sanitary service in England. In addition, there is the central agency, of the local Government Board with 14 medical officers and medical inspectors, whose time is entirely devoted to enquiries into special outbreaks, inspection work and control of local authorities.

This organisation is gigantic when compared with that in India, where the guidance and control of local sanitary authorities might be considered to be more needed than in England.

Bengal, one of the principal and most advanced provinces of India, which is more than $2\frac{1}{2}$ times the area of England and contains nearly $2\frac{1}{2}$ times its population, has a Health Officer for the metropolis, 48 Civil Surgeons, who are *ex-officio* Health Officers, and whose unsatisfactory position has already been alluded to, one Sanitary Commissioner and three Deputy Sanitary Commissioners. Were Bengal alone provided with the same strength of sanitary officers per population and per area as in England, then instead of four Sanitary and Deputy Sanitary Commissioners, there would be 35, and some 3,200 Health Officers. I am not including in this list the army of Sanitary Inspectors, who in England are necessarily more numerous than the Health Officers; nor Sanitary Engineers, of whom there is now a large number. This contrast will serve to shew the defenceless state of Bengal against disease, the absence of the possibility of efficient administration in health matters and the necessity for large and comprehensive changes. Moreover, that which prevails in Bengal prevails more or less and is necessary in Madras, Bombay, the N.-W. P. and Oudh, the Central Provinces, and the more advanced parts of the Punjab, Assam and Burmah. In the less advanced, I am inclined to think that the planter and road-maker are the best sanitary agents. Until the administration of public health is placed on something like a proper basis, it is premature to blame the local authorities in India for their incapability in coping with insanitary conditions. Without a strong local and central agency to guide and assist them the efforts of the local authorities at the best must be misdirected and costly, for sanitation is no exception to the rule which pertains to all specialties, viz., that knowledge is necessary for its practice.

The visits of the Sanitary Commissioner and his criticisms and advice in the shape of reports are infrequent and not well understood. The reports necessarily contain a dreadful picture of sins of omission and commission, and show

a large amount of work to be done. The effect on the local authority is bewildering as to how the suggested improvements should be made, succeeded by alarm as to prospective cost. A spasmodic and feeble attempt, of varying duration but never long, is usually made to do something, but the attempt soon breaks down and the old condition of affairs re-appears, while the plea of poverty and want of funds is brought forward as an excellent reason for letting things remain as they were. The usual phrase employed against nearly every proposed sanitary improvement is cost and want of funds. By repetition the expression has almost gained an axiomatic position in Indian sanitation, and is permitted to pass as something indisputable. In populous towns the cost must avowedly be great, for the requirements are large, and tax the ingenuity of the most economical sanitary engineers. Still it should not be forgotten that the funds available are also proportionately large. In small towns and villages it is quite exceptional for the necessary improvements to be beyond the resources of the locality, if these are carefully husbanded. It is not with the construction of large engineering works that the sanitation of the major portion of India has to be commenced. Were every municipality to-day made a present of the most costly schemes and placed in the best conditions as to its water-supply, drainage and conservancy, each would be in an unhealthy condition in the course of a year, were there no one with authority and special knowledge in the locality to supervise its public health.

As in other countries, three-fourths of the sanitary work to be done in India consists in the checking of epidemics and the strict enforcement locally of good sanitary laws, not so much by costly structural works—though in large cities these also become necessary—but by systematically and constantly removing, checking and preventing those conditions detrimental to health, which individuals, from ignorance, carelessness or greed, insist on establishing. For this purpose a knowledge of the laws of health and of their application to the conditions of city, town, village or district is requisite, which can only be acquired by special training. Progress can be made under no other conditions. The supposition that any body of men, be they ever so highly educated, municipal commissioners or others, in India or elsewhere, possess intuitively a knowledge of the laws of health and of preventive medicine and are able to apply that knowledge in a practical and effective manner, will not stand the slightest examination. It is obviously unsound, and a sanitary administration based on such an assumption would be mere charlatanism. For any effective administration a sanitary service of trained men is required, who shall be interested in the special work; and the question comes to be, how such a service shall be formed in India on the most economical and efficient plan. I suggest that it should be done by developing and enlarging for purposes of control, enquiry and scientific work, the existing imperial and provincial agency under the Sanitary Commissioner, and also by creating a new agency for local work. This new agency which should, as a rule, be indigenous in its nature, would open up to the Indian medical talent of the country a new field of activity and occupation. Both agencies would be so connected that,

in the event of particular individuals, distinguishing themselves and showing special aptitude in the local service, the reward would be promotion to the central service.

It is unnecessary here to enter into the details of a scheme of this kind. All that is necessary is to indicate the broad outlines which are as follows:—

1. The complete separation of the sanitation of the army and of the military cantonments from that of the civil population.
2. The special sanitary training of students in the medical and veterinary colleges and schools of India; and the affording to other classes of students facilities for obtaining, when desired, special training in sanitary engineering and architecture in the engineering colleges and technical schools.
3. The compelling of each municipality or combination or group of municipalities or local authorities to appoint a Health Officer after a certain date. Such officer's appointment, pay, leave, dismissal, etc. being subject to the approval of the Sanitary Commissioner.
4. The formation on every municipal board of a small but special sanitary committee with a medical man, and, when possible, the Civil Surgeon as President and the compulsory setting aside annually of a certain sum of money to be placed at the committee's disposal for sanitary work only.
5. The appointment of the Civil Surgeon on a proper remuneration with defined powers as Chief Consultant Health Officer of the district, and in those places in which he is not available either owing to overwork or other cause, the appointment of a special district Health Officer.
6. The placing of the local and district Health Officers in close relationship with the Sanitary Commissioner of the province.
7. The placing of the Provincial Sanitary Commissioners in touch with the Imperial Sanitary Office.
8. The representation of health matters to the Imperial Council.

To deal with the army first, I would remove the whole of the sanitary administration of the army from the Sanitary Commissioner with Government of India, and place it under the army medical authorities. The civil population is quite sufficient for the Sanitary Commissioner with the Government of India to deal with. The army should possess its own sanitary organisation, and it should certainly possess full control over its permanent military stations, and every cantonment should have a well defined and extensive neutral zone, separating it from the districts under the several local authorities around them. No one not really belonging to that cantonment should be allowed to live within that zone. The strip of land should be grass land and used for parade purposes, and a dairy farm might be placed on part of it, and directly under the control of the cantonment authorities. The present unsatisfactory condition of affairs in regard to cantonments may be seen by the members of the Congress at Dum-Dum a few miles from Calcutta. There they will see filthy bazaars, filthy businesses and filthy tanks in close proximity to the cantonment and a public road passing through the cantonment itself. In autumn last 64 natives and 2 Europeans were attacked with cholera

within a stone's throw of the British Infantry lines. Of the 33 deaths which occurred, the first 15 were around one tank and quite near to the cantonment bazaar. The Cantonment Magistrate lives at Barrackpur, of which place he has also charge. Both Magistrate and the Dum-Dum Municipal authorities were written to, but few steps were taken. A young medical officer, Surgn. Captain WINTER, who acts as assistant to the Civil Surgeon of the 24 Pergunnahs, did everything he could to allay the epidemic, but he had no special power. The military authorities were practically helpless, until I suggested that Surgeon-Major HARWOOD should take the matter into his own hands, quite irrespective of law or power, get the police to place a policeman over the infected tank to prevent people from drinking the water, and as soon as possible to empty a cartload of chloride of lime into the tank. Surgeon-Major HARWOOD succeeded in getting the policeman, who appears to have thought so lightly of his duties that he drank the water himself, and died of cholera within 24 hours. This had more effect on the inhabitants than any previous warnings, and deterred them from further drinking of the tank water, and in the meantime chloride of lime and phenyle were thrown into the tank. Other tanks, however, by this time had become polluted with the cholera organism, and it is impossible to know what might have happened, had not a filtered water-supply to the troops been just completed, and Surgeon-Major HARWOOD had the new supply promptly turned on, a standpost being conveniently situated on the very banks of the polluted tank. An interesting sequel to Surgeon-Major HARWOOD's throwing the cartload of lime and other disinfectants into the tank, is a letter from a pleader in Calcutta, threatening him with legal proceedings, unless he pays Rs. 400 to the man who leased the tank for fishing purposes. The fish of course died, and had to be promptly removed and buried. This account of Dum-Dum and its cholera will show that reform in sanitary matters in relation to the troops is urgently needed.

To pass on to the sanitary administration of the civil population, the first essential is a trained service, and the only way in which the material is to be obtained from which such a sanitary service can be drawn is by special education at the medical and veterinary schools and colleges. In vernacular and European medical colleges and schools a special course of hygiene should form a compulsory part of the ordinary curriculum. Something of the kind exists in the medical colleges, but it is far from meeting the requirements of the time. Special degrees and diplomas in public health might also be instituted, the examination for which should be open only to those who have undergone, in addition to the ordinary course of hygiene, a six months' practical training in public health and laboratory work. Aspirants to the position of Sanitary Engineers, Municipal Engineers, Secretaries to the smaller Municipalities, Superintendents and Sanitary Inspectors, should also possess a knowledge of sanitation, and opportunities ought to be afforded them of studying that part of sanitary science with which they may be called upon to deal, and for this purpose I would advocate that sanitary engineering and architecture should be taught at Seebore College in Bengal, as well as in the

technical schools, a certificate being granted to those pupils who have especially qualified themselves in these and kindred subjects bearing on sanitation. It must be admitted that certain expenses would fall on the Government in the appointment of a professor and assistant professors and the establishment of a properly equipped laboratory at each of the schools and colleges, but the cost might be reduced by the laboratories and staff being utilised for the sanitary examination of food, water and other articles sent by the municipalities in the district, a certain contribution being made by each of the larger ones according to its size and importance. An arrangement of this kind would secure a number of centrally situated laboratories, to which the whole scientific work of the surrounding districts could converge. It would save the larger municipalities the expense of providing a laboratory for themselves. It would insure an ample supply of articles at every medical school for teaching purposes, and it would furnish the Government with laboratories, where any particular kind of research pertaining to medicine could be carried on.

With a body of trained men ready, the next step is to compel every municipality or combination of local authorities, after a specified date, for instance in 1900 or 1902, to appoint a qualified Health Officer, whose duties would be to superintend the registration of vital statistics, the vaccination of those within his jurisdiction, and the sanitation of the locality under him. He would work with the especial sanitary committee in each municipality—an arrangement which by separating general municipal matters from those relating to sanitation would secure closer attention.

He would also be in direct communication with the Civil Surgeon or District Health Officer, and through him with the Sanitary Commissioner. The Civil Surgeon of the district, or specially appointed District Health Officer, would in some respects correspond to the county Health Officer in England and the Collector to the county authority.

Under the proposed arrangements there is no necessity for the Sanitary Commissioner of the province, who should be the Director of the department travelling about from place to place and performing the duties of an Inspector; nor would the Deputy Sanitary Commissioners occupy their time in general inspection, but devote their attention to enquiries into special outbreaks of diseases and their causes, to investigations into the causes of continued or special unhealthiness of particular localities and to visiting particular municipalities at the request of the District Health Officer made to the Sanitary Commissioner. Attached to the Sanitary Board, which is already formed, should be two or more Sanitary Engineer Inspectors to enquire into and report to the Board the cost, efficiency and character of any scheme of water-supply and drainage proposed by a municipality. It is not the function of the Board to draw up schemes for any local authority, but to check proposals that are costly, insanitary and inefficient.

Lastly, in any scheme of a sanitary service devised, no thoughtful sanitarian can lose sight of the fact that in a country like India sanitation is intimately connected with the food question. If 7½ millions people die annually

more than that number are born and live. Protection of the population by sanitary measures renders the number of mouths to be filled more numerous. Against this may be placed the fact that with a better state of health, permitting of more steady labor, food production is also increased. But it appears to me that the sanitation which limits itself to the diseases of man is very incomplete. Sanitary science deals not only with the diseases of man but with those of animals and of the vegetable world. A sanitary department should include in its duties the preservation of the cattle of the country from the murrains and plagues by which they are constantly attacked, and the preservation from pests and blights of the agricultural products of the fields. With that view, provision should be made for the investigation of these and the adoption of the best means of preventing them. The civil veterinary department should form a part of the sanitary service. The extra work done in the fields by the animals saved from epizootics with the extra produce and saving to the farmer, will develop an additional source of food supply, besides the milk and its products derived from the milch cows preserved from disease. Similarly that portion of the agricultural department concerned with disease of field or other produce should be amalgamated with the sanitary service of the country.

As, however, the investigation of disease, whether that of man, beast or plant, forms rather the scientific department of the sanitary service as distinguished from the administrative, this portion might be merged into one Scientific Institute for India, consisting of experts in the several branches and under the Sanitary Commissioner of India.

THE CURATIVE VALUE OF ARSENIC IN ASTHMA.

By ASSISTANT SURGEON H. D. PANT, L.M.S.

Gonda, Oudh.

THE treatment of well-established cases of bronchial asthma is so unsatisfactory, notwithstanding the host of remedies recommended in text-books, that in most cases we aim at nothing more than relief at the time of its paroxysm, allowing the patient to undergo the same agonies again and again at longer or shorter intervals to be again cut short by one or other remedy so profusely enumerated in books of medicine. Of course to treat rationally, it is absolutely necessary to find out the cause of the disease in every case and remove it as far as lies in the power of the medical man. This is the key note of medical science, but how far this is possible in treating cases of asthma, I leave it to practitioners who have had to deal with cases of this nature. On my part I confess I was not able to cure any cases of asthma which came under my treatment before I knew the value of large doses of arsenic given perseveringly for a month or more. I have also seen patients who had been under the treatment of both European and Indian medical practitioners for whom medical science had not done more than provide them with means of relief by resorting to all sorts of depressant, sedative and antispasmodic medicines whenever the fit came on.

A Deputy Collector, who had long undergone treatment at the hands of well-known medical men in Calcutta and elsewhere, used to tell me jocosely that I should find it worth while to make a *post mortem* examination of his body if he died here; for his stomach was a perfect apothecary's store, full of every available drug reputed for curing asthma, both old and new, rational and fashionable, costly and cheap, and that if he made a will, he would leave his stomach to me, that I might enrich my dispensary with its medicinal store. Under such circumstances any plan of treatment that holds out a reasonable hope of success in treating asthma cases is worthy of trial.

I must admit that my remarks are based on the successful termination of only three cases which had been under my treatment for a long time. Other cases which I have had to treat have not either undergone treatment for sufficiently long a time or have not been seen by me after the treatment was over, and consequently I am unable to say whether any permanent benefit resulted or not.

In the text-books, arsenic is mentioned along with quinine, iron, &c. as a valuable tonic in asthma, and if it has been used as such, it has probably been used in smaller doses or for a shorter time than is actually required to produce the desired effect of a complete cure.

I now give brief particulars of my first case:—Pandit B. a district engineer, aged about 40, had been suffering for the last two years from reflex asthma of gastric origin. In the beginning, the fits occurred on an average once a month, the patient enjoying good health in the intervals. Gradually the severity, duration and frequency of the fits increased to such an extent, that he was seldom free from cough and shortness of breath. He could not lie down after four o'clock in the morning owing to dyspnoea. He had to sit propped up till 8 o'clock, coughing and struggling for breath. Occasional exacerbations were added to these daily complaints brought on by and irregularity in meals and constipation, to which he was subject. He was under my treatment throughout, except for a few days, when, dissatisfied with my treatment, he tried some homoeopathic and Unani medicines, which he soon left off not finding in them the ready relief which my medicines always gave him in times of distress. His case went from bad to worse, till at last oedema of face appeared with constant dyspnoea. His urine was at this stage of a low specific gravity 1010° and contained albumen. I was rather alarmed, and strongly recommended a change of climate to which he did not consent.

It was about the middle of May 1893 when reading the *Lancet*, I came across an article in which liq. arsenicalis in ten drop doses twice a day at least for six weeks, along with dilute hydrochloric acid and nux vomica, in the morning, was recommended as almost a specific for asthma, I at once put my patient under this treatment, prescribing for him:—

| | |
|-------------------------|-----|
| R Acid Hydrochloric Dil | ℥x. |
| Tinct. Nucis Vomicae | ℥x. |
| Aque | ℥i. |

To be taken early in the morning.

| | |
|--------------------|------|
| R Liq. Arsenicalis | ℥x. |
| Spt. ammon : arom. | ℥xv. |
| Aque | ℥i. |

Twice a day, immediately after meals.

Improvement set in after two weeks, and after four weeks watering and redness of the eyes and itching of the lids, were complained of. I stopped the arsenic for a week and then recommenced it and gave it for two weeks more, thus making full six weeks as recommended in the *Lancet*. Within two months of the date of commencing treatment by arsenic my patient was an altered man altogether. Since then he has been enjoying perfect health. More than 18 months have now passed and he is quite free from all his old complaints and has never had a fit of asthma of any degree whatsoever. I may here remark that I had previously tried hydrochloric acid and nuxvomica in this patient for a long time without any benefit. The result must therefore be attributed to the arsenic alone.

Emboldened by this result, I tried the same treatment on the wife of my dispensary clerk, who had been under my treatment for over a month without any improvement. Six weeks sufficed to cure her, and she has not had any fits for the last sixteen months.

A month later another respectable woman was placed under my care. She had asthma of six years' duration. There was much difficulty in treating this case. Gastric irritability very often came on, requiring stoppage of the arsenic every fourth or fifth day. However, off and on, arsenic was given for six weeks as above detailed. Result perfect cure. No fits, and no cough for the last fourteen months.

In the last two cases fits of asthma came on an average every fortnight.

I wished to allow sufficient time to elapse before sending these notes for publication.

A MIRROR OF PRACTICE.

SCALP INJURY, FOLLOWED BY SYMPTOMS OF CEREBRAL PRESSURE: RECOVERY WITHOUT OPERATION.

By JOHN E. PANIOTY, L.R.C.P. Lond., L.R.C.S. Edin.

Resident Surgeon, Chandney Hospital, Calcutta.

W. B., a Eurasian lad aged 8 years, came with his mother to the out-door dispensary of the Chandney Hospital on the 26th November 1894 at about 10 A.M. His mother stated that last Friday, three days ago, a big boy hit him with an earthen tile on the head. There was some bleeding which she stopped by applying burnt rags. On Sunday, the 25th, the boy went with his father to the Entally Convent, and on their return home he got fever and passed a restless night. The next morning his face and head swelled a good deal.

When seen by me on the morning of the 26th, there was a lacerated wound on the right side of the head, about $3\frac{1}{2}$ inches above the inner third of the eyebrow, measuring $\frac{1}{2}$ inch by $\frac{1}{2}$ inch by $\frac{1}{2}$ inch. The bone was not exposed, and the forehead was swollen to the nasal bones. Healthy pus oozed from the wound. The pupils were normal, and responded to light. There were no signs of cerebral pressure. The boy had fever, 101°F . I advised the mother to take him to the Medical College Hospital, as I thought the injury a severe one, and I could not admit him to the Chandney Hospital, which is for natives only.

The mother did not do so, and the wound was antiseptically dressed. Next morning the swelling had completely gone down; the fever was much less, and the boy felt better.

On the 28th the mother told me the boy had had two fits at home, lasting for about two hours each time. He became insensible during the fit, but when he regained consciousness he talked and recognised every one. On the evening of the 28th November he walked with his sister to the dispensary, a distance of about $\frac{1}{2}$ of a mile, to be dressed. While waiting he had a fit at 6 P.M. and was in it till $7\frac{1}{2}$ P.M. He groaned and then became unconscious; there was foaming at the mouth and a turning up of the eyes. The muscles of the face and the right arm worked convulsively; the pupils were normal. Any pressure on the wound or on any part of the forehead excited immediate twitchings of the facial muscles. The wound appeared healthy. The boy never suffered from fits before the injury, nor is there any history of fits in his family. At the commencement of the fit he could be roused, but quickly relapsed into unconsciousness. Fearing the worst results, I sent for his mother and advised her to take the child to the Medical College Hospital, as operative measures, such as trephining, might become necessary, but she would not do so. I sent the boy home in a palkee, and advised the parents to apply ice to the head and keep him quiet in bed. I gave him a dose of stimulant mixture and prescribed the following:—
Spts. ammoniac aromat. ℥ 4, potassii bromidi grs. 2, aquæ ad. 3ij. every four hours.

On the 29th November the swelling had subsided, but the parts surrounding the wound were tender to touch, and the wound was healing healthily. The pupils were normal and acted to light; the pulse 70 and soft; there were no twitchings of the muscles nor any mental excitement. There were no signs of paralysis of any kind; the boy's memory was clear and he remembered of all that took place before or after the fits, but he had no recollection of having had any fits, nor had he warning of any kind that the fit was coming on. The same mixture was continued with the doses doubled.

On the 28th December the boy had four fits; on the 29th three fits; on the 30th and 31st two fits; and on the 1st, 2nd and 3rd December one fit each day, after which they ceased altogether. The febrile symptoms subsided on the 29th December. There was no sign of sepsis in the wound, and there was no external swelling or puffiness, except the day following the injury. In eight days the wound healed thoroughly, and the boy has been quite well since.

Remarks.—This case is remarkable for the absence of external signs to account for the very evident intracranial mischief. That the fits were due to cerebral irritation there can be no doubt, and the only explanation I would offer is, that commencing meningeal congestion, giving rise to grave manifestations, was suddenly cut short by early rendering the wound aseptic and ensuring the physiological equilibrium of the inter and extra cranial circulation by calmatives, such as ice, bromides, and notably rest. This case proves the great value and effectiveness of out-door dispensaries in affording timely relief, if only the sufferer is regular in attendance and faithful in carrying out instructions.

A CASE OF PNEUMONIA COMPLICATED BY A SINGLE AORTIC ENDOCARDIAL ABSCESS; WITH CLINICAL AND POST-MORTEM REPORTS.

By MANMATHANATH CHATTERJEE, M.B., Cal.

Senior House Surgeon, Mayo Hospital, Calcutta.

SITA NATH, a Hindoo male aged 22, was admitted into the Mayo Hospital, on the 6th November last, for the treatment of pneumonia.

History.—The patient states that eight days ago he exposed himself one night and got a chill. The next morning he had a severe attack of fever ushered in with a rigor. A cough soon followed the fever, with severe pain in the left chest. These symptoms continued unabated for seven days, when he sought admission into the Mayo Hospital.

Condition on Admission. The patient is rather sparsely built. There is an anxious look in his face; his lips are slightly cyanosed, and the tongue is coated with white fur. Breathing hurried and labored, 36 per minute. On percussion, dullness is found to extend from the mammary line in front to the axilla at the side, and to the spine of the scapula at the back, extending downwards to the base of the left lung. On auscultation, moist *redux* crepitations are heard all over the dull area, and friction sounds over the back of the lungs. There is an increase of vocal resonance over the whole of the affected part of the left lung. The expectoration is scanty, muco-purulent and sticky. The pulse is 126, soft and frequent. The heart sounds are normal and rhythmical but weak. The bowels are relaxed seven or eight times in 24 hours. Temperature 103.6°F.

Progress and Treatment.—From the nature of the symptoms, it is quite evident that the case is one of pleuro pneumonia. The patient was therefore put on the stimulant and expectorant treatment, with counter irritation over the back with liniment of iodine. He rallied with the above treatment. His temperature fell about 2°F and kept on fluctuating from 100° in the morning to 102°, in the evening.

Expectoration increased and became easy, and with it the sounds of the affected lung became moister, and in some places approached the character of gurgling rales. His general condition was much improved, and he felt much better.

On the 16th of November the temperature again rose to 103.2°F with an attack of shivering, but fell next morning to 99°F. On the 17th a peculiar "kick" was felt in the pulse which had become very soft with the fall of the temperature. On examining the heart no bruit was detected at the time, but towards evening a faint bruit was audible over the aortic region, which became very well marked the next morning, and was of the character of a loud regurgitant and obstructive murmur, conducted up the carotids and down the sternum. From this day the patient began to get worse, and the heart, which had already been weakened by one terrible ailment, failed, and the patient died on the 19th of November, in spite of the free administration of brandy and liberal nourishment.

I made a *post-mortem* examination of the body five hours after death. There was a thick layer of lymph on the posterior aspect of the left lung which was much enlarged and of a darker color internally. On incision the whole of the left lung was found in the stage of grey hepatization with a large quantity of purulent matter in the bronchioles and air vesicles of the lung. In fact there was the condition described in books as *purulent infiltration* of the lung. The right lung was healthy and quite crepitant. The pericardium was healthy. The heart itself was normal in size and its muscle structure was healthy looking. The right side of the heart—both auricle and ventricle—obtained *anti-mortem* as well as *post-mortem* clots. The endocardium was healthy and shining, and the valves were healthy. The left auricle contained some *anti-mortem* clots, the left ventricle also contained some *anti-mortem* clots entangled between the chordæ tendinæ and columnæ carnæ?

There was at the aortic orifice a small growth of the size of a large sized pea, situated between the diverging borders of the two contiguous aortic semi-lunars near their bases. The edges of the growth came a little on to the two valves, but were not adherent to them. The growth, however, came off with slight manipulation and was found to be simply composed of newly laid fibrin. It exposed a small abscess cavity with an irregular surface but with no signs of granulation.

The brain, the liver, the spleen and the kidneys were all healthy, and there was not the slightest trace of any other abscess anywhere.

Remarks.—This case is of clinical and pathological interest from two points of view—

1st.—The diagnosis of the cause of the heart symptoms. It is almost impossible to diagnose in life the *post-mortem* appearances that have been described. The symptoms point to an attack of endocarditis affecting the aortic valves.

2nd.—The pathology of the small abscess in this case is rather interesting, and appears to me to be thus:—A small colony of pus cells being carried by the pulmonary veins into the left side of the heart and thence through the coronary artery, was lodged in the site where the abscess formed. The sudden rise of temperature could, I think, be explained as due to suppuration and bursting of the abscess. It might be urged that if the abscess was due to the carrying of pus cells from the lungs, other abscesses would have formed in the liver, spleen and kidneys, as is the nature with pyæmic abscess. It might be said that the case was one of ulcerative endocarditis; but it should be remembered that there was an entire absence of endocarditis in any other part of the arterial and cardiac system. The completely healthy appearance of the semilunar or mitral valves to which the abscess was so close, and the presence of this affection in more than one place and over the valves especially, which is so characteristic of endocarditis of any form, points more to an abscess than to endocarditis. I might also add that my belief is, that if the patient had survived a few days longer, other abscesses might have developed in other organs. This complication, however, seems to me to be a very rare one.

SUICIDAL THROAT-WOUND, CUTTING DOWN TO THE OESOPHAGUS AND CAUSING LOSS OF SPEECH AND DEGLUTITION: COMPLETE RECOVERY.

By JOSEPH BENJAMIN, C.M.S.

Ahmedabad.

WHILE I was in charge of the Taluka Dispensary at Parant, CHULAJI BHAIJI, a Hindu male, *et. 55*, was sent to me by the Police the on 2nd September 1891, for the treatment of an incised wound of the throat, about three inches long, one inch wide, and about the same in depth, directed transversely from the left to the right. The windpipe was found divided almost completely below the pomum Adami, only a slight portion remaining undivided at the back. Bubbles of air were passing out of the upper opening of the wounded larynx. The patient was unable to speak or to swallow anything. On admission there was no hemorrhage from the wound. There was a free discharge of thick mucus from the lower opening in the larynx. The large vessels of the neck were unhurt. The patient was prostrated but conscious; he had slight fever, and his pulse was weak. He had cut his throat with a knife after killing his nephew by stabbing him with the same weapon, as he suspected him to be in illicit intercourse with his wife.

Treatment.—The wound was cleaned and stitched at the sides only. A tracheotomy tube was passed into the lower opening of the injured windpipe and secured by means of a tape, to prevent the accumulation of the thick mucus which troubled his breathing. Carbolic dressing was applied to the wound and an aperture left in the dressings for the ingress of air into the windpipe. The head was kept bent downwards and forwards by means of a bandage to the chest and head, and the patient was fed with a stomach pump tube.

7th November.—During the patient's stay in hospital he had slight fever for the first few days, became excited and boisterous, and had to be restrained by force to keep his hands off himself. He was bandaged, as it was feared he might put an end to his life. As the fever subsided he quieted down, and his further progress was uneventful. The tracheotomy tube was removed on the fourth day and the wounds in the trachea and oesophagus healed within another fortnight. On the second day after removing the tube, the patient quite recovered his voice and the powers of speech and deglutition. He became somewhat emaciated from diarrhoea, but with careful dieting, he soon recovered his wonted health and strength. He was discharged perfectly well on the 7th November.

A CASE OF ABSCESS OF THE LIVER, TREATED BY TWO ASPIRATIONS AND THEN BY FREE INCISION AND DRAINAGE: RECOVERY.

By SURGEON-CAPTAIN C. W. R. HEALEY, A. M. S.
*Medical Officer in charge, of Cantonment General
Hospital, Lucknow.*

[REPORTED BY MAULA BUKSH, M. H. A.]

KALLOO, *et. 40*, Mussulman male, was admitted into the Cantonment General Hospital on the 23rd July 1894, complaining of a daily rise of temperature and pain over

the hepatic region. He had been suffering for five months, and was much debilitated and had lost flesh considerably. On examination a swelling was detected on the right side, extending from below the costal arch to the middle-line. It was tender to pressure and quite fixed. The tongue was coated and foul; there was loss of appetite and the bowels were constipated.

There was an evening rise and a morning fall of temperature daily. A hypodermic needle was inserted into the swelling and a small quantity of yellow pus withdrawn. Deslfoy's aspirator was now employed and 14 ounces of yellow pus, slightly blood-tinged, was removed, and the abscess cavity was thoroughly washed out with a warm 5 per cent. solution of boric acid. An antiseptic pad was placed over the puncture made by the needle, and a tight bandage applied round the body. Next day the temperature was normal and remained so for a few days, the patient feeling a good deal better and suffering much less pain. He was given a . . . and kept in bed on fluid diet. The sac however began gradually to fill again; the temperature rising every evening from 101 to 102°, and the patient complaining of considerable pain over the hepatic region. He was again aspirated and the sac thoroughly washed out. This time the pus was less in amount (5 ounces) very thick and of a brick-dust color. The relief was only temporary, for the temperature began to rise again, and he suffered from very profuse sweating. He was now placed under chloroform, and an incision was made over the sac of the abscess. This was gradually deepened, and finally by means of the finger, the abscess cavity was reached deep down in the liver substance. It was thoroughly washed out, and a drainage tube, about the diameter of the little finger, was inserted down to the bottom of the cavity. The wound . . . dressed twice daily and soon began to shew signs that the cavity was contracting. After this he convalesced rapidly and was discharged quite well on the 25th September, about a month after the operation.

CHLORIDE OF CALCIUM IN THE TREATMENT OF ACUTE PNEUMONIA.

DR. A. CROMBIE in the *Indian Medical Gazette* calls attention to the value of chloride of calcium in pneumonia. DR. M. MOIR, of the Indian Medical Service, confirms this opinion of its value in an article in *The Practitioner*. DR. CROMBIE believes that in lobar pneumonia . . . of calcium reduces the temperature and keeps it within safe or normal limits, in spite of the continuance of physical signs; (2) that there is a tendency for the morbid process to be arrested at whatever stage the drug is given in efficient doses, and that the course of the disease is thus shortened or rendered milder; (3) that there is a singular freedom from all anxiety, distress, and danger, a freedom not usually associated with continuous high temperatures; (4) and that there is a corresponding reduction in mortality.

DR. MOIR reports two cases in which the symptoms were alleviated by the administration of this drug. He gave it in doses of from sixty to ninety grains daily (ten or fifteen grains every four hours).

Many drugs have a reputed value in pneumonia, but none are yet accepted as in any sense standard remedies in the disease.

The evidence in favor of chloride of calcium is sufficient to demand for it some attention, and we can only trust that further experience will show that the drug is additionally useful.

Yours sincerely
S. B. Partridge

OUR PICTURE GALLERY.

SAMUEL BOWEN PARTRIDGE, C.I.E.,

F.R.C.S. Eng., F.R.C.S. Edin., F.K.C. Lond., F.O.U.

Deputy Surgeon-General, Indian Medical Service.

THE patriarchal bust which adorns our PICTURE GALLERY, outtrays a personality which either as a professional genius or as a kind and noble-hearted gentleman, is seldom equalled but never surpassed in those qualities of head and heart that make a man loved and revered such a man was SAMUEL BOWEN PARTRIDGE. He was born in 1828 and was educated at King's College, London. He studied medicine at King's College Hospital, where his natural talents and ability, aided by the well-known teachers of that famous school, gained for him a high place in the examinations of the Royal College of Surgeons in 1850. He entered the Honorable East India Company's Indian Medical Service as an Assistant Surgeon in 1852, and immediately upon his arrival in Calcutta he was sent to the field of war in Burma, where he served throughout the long months of that weary and burdensome campaign, for which he obtained a medal. In 1853 he served for a few months as Surgeon to the Loodiana Regiment, and then as Civil Surgeon of Midnapore. While here, he was deputed to accompany SIR FREDERICK HALLIDAY, the first Lieutenant-Governor of Bengal, as his personal Surgeon, in a tour through Tirhoot. In 1855 he was appointed Professor of Materia Medica in the Calcutta Medical College, but the threatening and troublous times of the mutiny caused him to be sent to Oudh, where he was placed in medical charge of the 2nd Oudh Irregular Cavalry at Lucknow. Throughout this arduous and eventful campaign he faced all the fiery trials and rigorous difficulties that were shared in equal measure by the officers and staff and by the rank and file of our Army. He was one of the beleaguered garrison in the Residency with SIR HENRY LAWRENCE and his brave comrades, shoulder to shoulder with his renowned colleague and friend—JOSEPH FAYRE—and many other heroic Surgeons who fell in that ably defended but flimsy shelter, holding their own against unnumbered odds and in the face of indescribable dangers and difficulties. When relief came and SIR COLIN CAMPBELL's brave little army freed the beleaguered garrison, PARTRIDGE accompanied the main troops and was present at the fierce engagements of the storming of Alum Bagh, Cawnpore, Fattahghur, Kalandi, and the siege and capture of the city of Lucknow in 1858. For his excellent services throughout the Indian Mutiny he was honorably mentioned in the military despatches and obtained a medal and two clasps, besides special promotion to a Brevet Surgeoncy. His brief connection with the chair of Materia Medica at the Calcutta Medical College, had already won for him a name as a teacher, and at the close of the Mutiny, he was appointed Professor of Anatomy at the College and Second Surgeon to the Calcutta Medical College Hospital. This nomination gave full scope to his natural abilities. His forte was Anatomy and Surgery, but he was recognised as an "all round good man," for he could fit himself aptly and creditably into any "chair." Hence he sometimes "officiated" in the chair of Chemistry and Physics, at other times he

gave lectures in Botany and Pathology, while for some time he lectured in Medicine and filled the office of the Principal of the Medical College. On the retirement of SIR JOSEPH FAYRE he was promoted to the First Surgeoncy of the College Hospital and to the Professorship of Surgery in the Calcutta Medical College. He was also appointed Consulting Surgeon to the Howrah General Hospital, and, like most men of his excellent service, he filled a plurality of offices at one and the same time, for he was also Medical Inspector of Indian Emigrants, Examiner in Anatomy and Surgery to the Calcutta University, President of the Faculty of Medicine in the University, and Vice-President of the Asiatic Society of Bengal, besides having an extensive consulting surgical practice.

On the 1st January 1880, DR. PARTRIDGE retired from India after 27 years' service, 21 of which were spent in building up the great educational reputation of the Medical College of Bengal. In attempting to describe his work and worth we cannot do better than place on record the sincere and well-deserved eulogium of Dr. J. M. COATES, who was then Principal of the Calcutta Medical College, as found in his Report on the 25th Session of the College, in these terms:—

"PROFESSOR S. B. PARTRIDGE was a truly great surgeon, yet so humble and unobtrusive, that it was only those in actual contact with him who knew and felt his value. A short acquaintance with his genial, loving nature, quickly induced an unbounded regard, and the mature, almost faultless judgment, felicitous expression, fertile resource and quick decision, compelled an unlimited admiration.

"Had this accomplished surgeon but published his own surgical work and the experience he acquired in so large a field, both in war and peace, and especially in our hospital, the world would have known how great a surgeon was amongst us.

"His service began with the 2nd Burmese war in 1852. In the mutiny he was in the centre of the fiercest of the struggles of that terrible time, the Residency of Lucknow, the retaking of Cawnpore, Kalandi, Fattahghur and the final siege and capture of Lucknow. During the greater part of this campaign he served as Field Surgeon with the Head-Quarters of the Army.

"But it was his long connexion, extending over one and twenty years, with this College and Hospital that has left his impress on us and endeared him to our College alumni.

"One of his pupils told me that listening to DR. PARTRIDGE's lecture was the most delightful of his enjoyments—so complete yet so concise, so clearly reasoned and yet so pleasingly presented, that the knowledge and the pleasure strove for supremacy.

"And what an operator! The eagle's eye, the lion's heart, and the lady's hand could not have been more fitly combined nor better illustrated. The present generation of surgical students and practitioners must pass away from Bengal ere DR. PARTRIDGE's influence and teaching shall cease to have its effect on the people of this part of India.

"I will not give up the hope that Government may yet honor one so gifted and useful as our late colleague. There is not a man of our service who would not feel that we were all honored by such a recognition of DR. PARTRIDGE's service."

These are the expressions of a man who himself was an honored teacher, a skilled administrator, an able physician, and a generous and true hearted friend, a man loved and respected in his retirement, as was the grand subject of his well-merited and enthusiastic praise.

be ascertained by *post-mortem* or experimental examinations, for which in India there is abundant material. Good dissections of the lymphatics in filarial disease are therefore still a desideratum. It would be well to warn intending investigators of the fact that the filaria is not usually found in the blood or tissues in developed elephantiasis. It would appear that the development of the disease brings about in some way the destruction of the parasite which produced it. In the treatment of filariasis MAITLAND has recently advocated the excision of filarial glands.

GUINEA WORM

Tox is a subject which demands investigation, and one which, though energetically pursued by medical men in India in earlier times, has been virtually abandoned by the present generation of Indian medical men.

OF DYSENTERY, LIVER ABSCESS AND AMOEBA COLI

Our views are vague, various, and uncertain; admitting, as we must, the inter-relationship of liver abscess and dysentery, but remembering that liver abscess rarely accompanies or follows dysentery in cold climates, that it is more common in connection with the dysentery of certain districts in warm climates than in connection with that of other districts, and that it appears more frequently in certain epidemics of dysentery than in others, the question arises: Are not these apparent anomalies to be explained by the supposition that there are several kinds or species of dysentery, all of which are not etiologically in relationship with liver abscess? There is surely some false doctrine as well as much confusion of ideas at the bottom of the classification of liver abscesses into single abscess, which is designated tropical, and multiple abscess which is designated dysenteric, secondary pyemic abscess. Both forms occur in the tropics, occur in connection with dysentery, and both are microscopically identical in physical characters. A nomenclature, which implies pathological differences as existing between these various merely numerically different forms of abscess should be expunged, until it is proved that there is a real difference. The amoeba coli is a parasite which all physicians in India ought to make themselves practically familiar with. It is found in dysenteric discharges and in the pus of liver abscess. COUNCILMAN, LAFLER and OSLER regard this organism as the specific cause of a particular type of dysentery, and also as a cause of liver abscess. LEWIS and CUNNINGHAM declared against the pathogenic qualities of amoeba coli for the reason that the same or a similar organism is frequently found in healthy conditions of the alimentary canal. But under such conditions as catarrhal inflammation of the bowels or ulceration of the bowel, may not the amoeba attack weakened tissue and give rise to complications and dangers?

BERI-BERI.

All the more important recent advances in this subject we owe to foreigners or to our own countrymen working in many different places, but not in India. Very little has been said in recent years about the distribution of beri-beri in India. The disease is seen in London among the lascars crews of ships coming from Bombay. It is presumed therefore that the disease is endemic in Bombay; and if in Bombay, probably elsewhere in India, where we find

in most respects those conditions of climate and insanitation which in Japan, in China, in Brazil, in Africa, in the West Indies and in the Malay Archipelago give rise to this very dangerous disease.

ANKYLOSTOMIASIS.

A vast amount of sickness among the coolies on tea plantations and among the natives of certain villages in Assam and in Ceylon has been caused by the ankylostomum duodenale. Doubtless much of the anæmia, so prevalent among natives, is attributable to this parasite; and the general appreciation by the profession of this fact, a knowledge of the methods of diagnosing the presence of the parasite in the alimentary canal, and of the use of thymol as a remedy, will save many a life and much invaliding and suffering. DOBSON'S investigations have shown not only that the ankylostomum is widely distributed throughout India, but that several other species of entozoa which were formerly looked upon merely as varieties and helminthological curiosities are by no means uncommon.

CHRONIC INTESTINAL FLUX.

Forms of this are exceedingly common, particularly in Europeans in India, as in all hot countries. They are of different kinds and acknowledge different causes, *e. g.* chronic dysentery, visits to cooler health resorts constituting "hill diarrhoea," chronic diarrhoea associated with relapsing catarrhal inflammation "characterised by sore-mouth, pale fermenting loose massive stools which, if not corrected, early terminates in chronic physiological starvation and ultimately in death. Then we have "morning diarrhoea" which, judging from the peculiar acrid bilious nature of the stools, seems to be caused by sudden and excessive hepatic activity; diarrhoea dependent on portal congestion, and other fluxes, all of which should be studied, distinctly separated, and defined.

TYPHOID FEVER.

The separation of typhoid fever from the malarial group is one of the best pieces of work which of late years is to be credited to the profession in India. There is only one point of interest that can be here referred to, *viz.*, that the typhoid germ in India may have a somewhat different history from what it has in England. Typhoid in England does not often, if ever, arise *de novo*. Epidemics of typhoid in England generally succeed, and can almost invariably be traced to the arrival of a case of the disease in the district subsequently affected. It is as if the typhoid germ, although able to live for a time, must be resuscitated, so to speak, by passing occasionally through the human body, but in certain warm climates the germ of typhoid is a native of the soil, and needs no periodical resuscitation in the human body to confer on it pathogenic properties, or to keep it in existence as a species. If this view be correct, the sanitary measures at present in vogue are inefficient.

CHOLERA.

There is no possible excuse for hesitation for accepting the dogma that in India as in Europe cholera is a filthy disease, carried by dirty people to dirty places; that its common mode of access to the interiors of these people

is by the water which they drink, and that it may properly be described as a water-borne disease, by which is meant that it is caused by a poison which is swallowed and which in ninety-nine cases out of a hundred is carried to the mouth in water. In some very rare unproved cases, perhaps where cholera is very rife, and filthy habits are overabundant, it is blown by gusts of wind or carried by the hand into food and swallowed. It is not a mere matter of rivers and watersheds, but of cooking utensils, drinking cups, water-bottles, and especially of cisterns and reservoirs. Inside the body the poison passes, after killing the patient in its passage; outside its course is halting, erratic, various in manner and intensity, depending largely on the physical surroundings in which it finds itself (the soil, the water, the temperature) by which oftentimes it is destroyed, or amid which it dies out. The varied susceptibility of individuals points to varied powers of digesting and thus destroying the contagion.

INDIA'S REAL WANT IS PURE WATER.

The difficulty of meeting it is largely one of expense; and this is no small obstacle. Sanitary efforts then will have to be mainly occupied in endeavouring to keep clean the supply which already exists. The most efficient of the many systems for the purification of the water supplies of great towns is ANDERSON'S Revolving Purifier. There are, of course, conditions other than the provision of pure drinking water to be considered in relation to the pathology and epidemiology of cholera; but, as DR. SOLOMON SMITH has lately pointed out, the production of an epidemic is analogous to the opening of a 'word' lock. As all the letters must be placed in position before the lock could be opened, so many factors must combine before an epidemic of cholera could be caused. We know that one essential cause of cholera one letter to the lock, is the swallowing of the poison; and thus, by a provision of pure water, we are able to break up the combination by which alone an epidemic could be produced.

AN INDIAN SANITARY SERVICE.

To save the Mahomedans from the danger caused by their pilgrimages, to save the world from the danger caused by Mecca, the following steps should be taken:—

1. The Indian Sanitary Services should be organised on the following basis:

(a) An Imperial Sanitary Department attached to the Government of India and distinct from the sanitary department of the Army. It should consist of (1) the Sanitary Commissioner with the Government of India, (2) a Deputy Sanitary Commissioner, (3) a medical Statist, (4) a Veterinary Commissioner, (5) a Sanitary Engineer, (6) a Minister of Health having a seat in the Viceroy's Council, as President. There should be a laboratory with trained experts.

(b) A Provincial Sanitary Department attached to each of the provincial governments and consisting of (1) Sanitary Commissioner, (2) Assistant Sanitary Commissioner, (3) Sanitary Engineer, (4) a President who should be a high officer in the Civil Service; also travelling agents and scientific agents.

(c) A local sanitary department attached to each Municipality, District Board, &c., and consisting of Municipal Commissioners or District Magistrates with Civil

Surgeon when obtainable. Executive agents: A Health Officer attached to one or more towns; an Engineer in a similar position, and a sanitary staff for each place as required.

2. A complete sanitary regulation of all Indian fairs should be undertaken.

3. A rigid system of medical inspection of all pilgrims should be instituted at the ports from which they start, the sick being detained, and the healthy alone being allowed to proceed.

4. The medical inspection at Karaman should be so conducted as to secure its complete efficiency. Qualified medical women, and if possible, Mahomedan women doctors, being among the inspectors.

5. At Jeddah the sick would again be wooded out.

6. The sanitation of Mecca should be thoroughly reorganised under the auspices of the Turkish Government. The "water-supply" inspected and protected, and the poison well Lemzem cleaned and provided with a larger supply and a continual change of water.

7. A complete system of conservancy should be carried out during the time of the pilgrimage, all refuse immediately removed and sick promptly isolated.

TROPICAL RESEARCH.

Until not very long ago, all that was best and most valuable in the science and practice of tropical medicine was almost entirely of English creation, but it is now an ugly fact that in tropical pathology, in the investigation of tropical disease, and in tropical medical literature, we are decidedly on the wane; and England with her unbounded opportunities is not *facile princeps* in tropical medicine. The Englishman displays unlimited courage and devotion to duty when a pestilence breaks out in a colony, but leaves the scientific part of the work, the pathological investigation, to Japanese, French, Germans and other outsiders.

RESEARCH IS NOT ADEQUATELY ENCOURAGED IN INDIA.

There are several obstacles to the successful cultivation of medical research in India. (1) It is not officially encouraged. In fact the younger and more scientifically ambitious medical officers in India feel that those who trouble officialdom for the investigation of any new scientific facts that may occur to them are regarded as nuisances; and as promotion, as a rule, depends on seniority, on avoiding giving trouble at head-quarters, and on respectable conservatism, the pathologist is out at elbows and is nobody, while the diplomatic senior officer has all the plums. (2) The time of medical officers is taken up by an amount of unnecessary clerical work being imposed on them. (3) The want of regular instruction in tropical diseases in English medical schools. English medical practitioners, excepting those who have had the privilege of passing through Netley, begin their practice in the tropics with no knowledge of tropical diseases, so that by the time they have passed the years necessary to be familiar enough with the subject and to be in a position to add anything to the common stock of knowledge about it, the energy and enthusiasm of youth have passed and their career in the tropics is about over. (4) While the combatant officer goes home at the public charge and to an appropriate and well-furnished school

to keep himself abreast of the times in guns and torpedoes, a medical officer has to go home at his own expense and to pay for his attendance at some hospital or laboratory if he wishes to brush up his knowledge of life-saving machinery.

The suggestions made with a view to remedy the foregoing defects are :—

(1). To make promotion in the medical services, in greater measure than at present, a reward for medical merit.

(2). To give at the public expense to deserving and suitable medical men an opportunity to return occasionally to Europe for a year or two to brush themselves up in medical matters and to familiarise themselves with new methods.

(3). To have less clerical and more medical work in the services.

(4). To have the examining and graduating bodies in Britain to give at least one question in their examination papers in medicine on a tropical disease.

(5). To have the large hospitals in Liverpool and London in which tropical diseases most abound, affiliated with the local hospital medical schools in some way.

THE REPRESENTATIONS OF THE INDIAN MEDICAL ASSOCIATION TO GOVERNMENT, ON THE GRIEVANCES OF CIVIL ASSISTANT SURGEONS AND CIVIL HOSPITAL ASSISTANTS.

IN compliance with the notices issued, the third meeting of the Council of the Indian Medical Association was held at its Library on the 24th January. Present, DR. LAL MADHUB MOOKERJI, in the chair, DR. K. G. SIRCAR, J. G. ANDERSON, MONKEY LAL DUTT, H. C. HODGKINS and J. R. WALLACE. After reading and confirming the Minutes of the 2nd meeting of the Council and of the First Annual General Meeting of the Association and after duly electing the twenty-nine members who had applied since the Council's last meeting to become members of the Association, the report of the President and Secretary and the letters relative thereto, on the subject of representing to Government the grievances of Civil Assistant Surgeons and Civil Hospital Assistants, were considered, the letters were passed, and signed by the Council and were formally sent to the authorities on the 29th January 1895, in the following form :—

To

Surgeon Major-General

W. R. RICE, M.D., C.S.I.,

Surgeon-General with the Government of India.

Sir,

WE have the honor, on behalf of the Indian Medical Association, and of the parties concerned, to lay before you the following representation of the grievances of Assistant Surgeons of the Civil Medical Department of the Presidential and Provincial administrations under your command.

1. That though the standard of qualifications of Civil Assistant Surgeons, both classical and professional, has been greatly enhanced and their duties and responsibilities

heavily augmented since the formation of this service in 1841, the status, salary, prospects and pension are the same to-day as they were 50 years ago. That as compared with other State services locally recruited, such as the Judicial, Engineering, Educational, Revenue, Administration, etc., an Indian or Anglo-Indian Subordinate of inferior academic qualifications than an Assistant Surgeon, has the prospect of rising to the highest position in the service to which he belongs, while the emoluments of these various locally recruited State services, when compared with the emoluments of Assistant Surgeons, are a cause for serious dissatisfaction, and become a grievance of a very marked character indeed.

The fact that an Assistant Surgeon's maximum salary is Rs. 200, that his travelling and officiating allowances are out of all proportion to the expenses necessary for the up-keep of his position, and that his professional work and worth find a most unsuitable recompense when compared not only with his own compeers in other subordinate services, but also when compared with junior medical practitioners having inferior qualifications, exhibits a strange and disparaging anomaly. It is important in this connection to point out that the work of Assistant Surgeons in the medical charge of districts, civil hospitals and dispensaries, as well as jails, and the supervision of vaccination and rural sanitation, is admittedly large and onerous.

As a case in point for comparison of two subordinate services, it may be stated that a First Grade Assistant Surgeon is paid a fourth of the salary of a Deputy Magistrate. These two subordinate services, when first created, were on the same footing with regard to pay and prospects. At the present time the Subordinate Deputy Magistrate, of 14 years' service, draws a salary of Rs. 800, while the Assistant Surgeon of 14 years' service draws only Rs. 200. It is argued in connection with the small salary paid to Assistant Surgeons that they are allowed private practice. It is admitted on all sides, however, that the work of these subordinate officers is so burdensome that they have little or no time for private practice, so that their added remuneration from this supposed source of income in no way represents adequate emoluments, while the ever-increasing additions of qualified practitioners to the field of private practice, makes the prospect of an income from such a source still more diminutive.

It is maintained that their impecuniosity has greatly handicapped their social status, rendering their condition both socially and pecuniarily one of great hardship.

2. That with regard to prospects, though Assistant Surgeons are eligible for promotion to the Unconvenanted or higher Civil Medical Service, they are not so promoted. There is therefore no avenue or prospect of promotion open to the Assistant Surgeon beyond the three grades of his own service, which terminate with a maximum salary of Rs. 200, with no other title or rank than that of Assistant Surgeon and a pension of Rs. 100 after 30 years of laborious work.

3. With regard to status, it is felt, that when compared with other subordinate services, the position of an Assistant Surgeon is very ill-defined, that he is subjected to the restrictions of the Arms Act which does not affect his

compeers in similar subordinate services, and that in such State establishments as Levees, Durbars, etc., he is without any definite status, and that the absence of some official recognition of his position, tends to degrade him and his class socially among his countrymen.

We have carefully considered the voluminous statements of the grievances of Civil Assistant Surgeons as published by them in the *Indian Medical Record*, the organ of the Association and of the local profession, but we feel that the lengthy correspondence referred to, resolves itself into the points raised in this communication, and we do not desire to trespass too much upon the time and patience of the Indian Government.

With this brief statement of the grievances of Assistant Surgeons, the Council of the Indian Medical Association, as representing the local profession of this country, desires most respectfully with a view of offering such help as it may towards the settlement of this important problem, to offer the following suggestions for the kind and gracious consideration of the Government of India, viz :—

I. That Civil Assistant Surgeons be designated Assistant Civil Surgeons and that their service be merged into the present Uncovenanted Medical Service under the title of the *Indian Civil Medical Service*.

II. That such service be graded as follows :—

(a). Civil Surgeons (as at present graded in the Uncovenanted Medical Service).

(b). Senior Assistant Civil Surgeons. A new grade, promotion to which will be made after 20 years' service, for special merit.

(c) First Grade Assistant Civil Surgeon.

(d) Second Grade " "

(e) Third Grade " "

3. That the grades, salary and pension be arranged as follows :—

Tabular Statement showing Grades, duration of Service, Salary and Pension in such Grade, together with Allowances of the Indian Civil Medical Service.

| GRADERS OF (J. C. M. S.) | Service for Grade. | Salary | Pension | Allowances. |
|-------------------------------------------|-----------------------|--------|---------|-----------------------------------------------------------------------|
| 1. Civil Surgeon* | | Rs. | Rs. | * |
| 2. Senior Assistant Civil Surgeon. | (Special) | 500 | 250 | The same as Civil Surgeons |
| 3. First Grade Assistant Civil Surgeon | 25 years | 400 | 200 | (U.C.M.S.) when in officiating charge. |
| 4. Second ditto. | 20 " | 350 | 175 | Grade allowances same as the Subor- dinate Judicial Service. |
| 5. Third ditto. | 15 " | 300 | 150 | |
| | 10 " | 250 | | |
| | 5 " | 200 | | |
| | | 150 | | |

* Or present Uncovenanted Civil Medical Service, as it stands.

Having respectfully submitted the foregoing suggestions regarding change of service and grade designation, for better prospects in regard to promotion, pay, travelling and other allowances and pension, it now remains to mention the subject of official status.

In this matter we feel that the justice and merits of the case would be suitably met by according to the Assistant Surgeon class, the same public status as is at present recognised for the Subordinate Judicial Service.

In conclusion, we would most respectfully beg your

generous consideration and support of this communication, as we feel that your recommendations for the amelioration of the grievances of Civil Assistant Surgeons will tend not only to the contentment and gratification of a large and worthy section of State servants, but will be the means of signal encouragement to medical education and progress in our Indian medical schools and colleges.

We have the honor to be

SIR,

Your most obedient servants

Lal Madhub Mookerjee, Rai Bahadur, L.M.S., F.O.U.,

President.

E. W. Chambers, L.M.S., L.S.A. Lond. and F.S.C.S. Lond.

Vice-President.

K. G. Sircar, M.B., L.R.C.P. Edin.

Money Lal Dutt, M.R.C.P. Lond.

H. W. Jones, M.D., M.R.C.S., Lond.

H. C. Hodgkins, *Treasurer.*

James R. Wallace, M.D., *Secretary.*

*Members of
Council.*

To

Surgeon Major-General

W. R. RICE, M.D., C.S.I.,

Surgeon-General with the Government of India.

SIR,

On behalf of the Indian Medical Association and of the parties represented, we have carefully considered the disabilities and grievances of the Civil Hospital Assistants in the various Presidential and Provincial administrations under your command.

The representations of these subordinates have been fully made known in the *Indian Medical Record* from time to time during the past five years, and it is with a view of respectfully placing a brief statement of their disadvantages and difficulties before you and of soliciting your generous help for their amelioration, that the Council desire to, approach you with this representation.

Briefly, the grievances of Civil Hospital Assistants may be classed under two heads :—(1) Status, (2). Pay, Allowances and Pension.

1. *Status.*—It is admitted that of recent years the educational and professional training of Civil Hospital Assistants has been greatly improved. They now undergo a full curriculum of four years' medical education, and are recognised officially as qualified practitioners of a subordinate grade. They are ordinarily made to fulfil the duties of assistants to Civil Surgeons, but they are frequently placed in independent charge of small districts, dispensaries and jails, and are largely used in promoting the work of rural sanitation and vaccination. It is felt that in keeping with these onerous duties the title of Hospital Assistant is a misnomer, since the compounders, dressers, and other menial servants of a hospital, are also known as hospital assistants. This appellation serves to keep them low in the social scale, and it is felt that a change of designation to that of Sub-Assistant Surgeon would adequately describe their professional and subordinate position, and at the same time remove a grievance which is the cause of much heart-burning and dissatisfaction.

2. *Pay, Allowances and Pension.*—There are three grades of Civil Hospital Assistants. The lowest receives a salary of Rs. 25 monthly, which, after seven years, constituting the second grade, is raised to Rs. 35; following which is the highest grade, which is entered after fourteen years' service, and has a salary of Rs. 55. The independent charge of dispensaries is attended with an additional ten rupees per mensem.

In comparison with similar subordinate grades in the Public Works Department, Police, Judicial, Revenue Departments, &c., the pay, prospects and general allowances are very meagre indeed; thus a Sub-Overseer in the P. W. D. can rise to be a Sub-Engineer on Rs. 400 per mensem; a sergeant of the native police can rise to be an Inspector on Rs. 200 per mensem; while subordinate clerks in the Sub-Judicial and Sub-Revenue departments, have an avenue of promotions open to them, which yield emoluments varying from three to six hundred rupees per mensem. In none of these subordinate services is the educational and professional training as rigorous as that required for this section of the subordinate medical service. It is felt that a small increase of salary and pension for each grade of Civil Hospital Assistants and the creation of a special senior grade, promotion to which would be made for special merit and qualifications, would fully meet the disadvantages under which they at present labor.

3. *Tabular Statement shewing Grades, duration of Service, Salary and Pension in each grade, together with allowances.*

| GRADE OF SUB-ASSISTANT SURGEONS. | Service for Grade. | Salary | Pension | Allowances. |
|----------------------------------|--------------------|--------|---------|-------------|
| | | Rs. | Rs. | |
| 1. Senior Grade | (Special) | 100 | 50 | |
| 2. First " | 25 years | 80 | 40 | |
| 3. Second " | 20 " | 70 | 35 | |
| 4. Third " | 15 " | 60 | 30 | |
| 5. Fourth " | 10 " | 50 | ... | |
| 6. Fifth " | 5 " | 40 | ... | |
| 7. Sixth " | | 30 | ... | |

We respectfully solicit that the foregoing suggestions may meet with your kind approval and recommendation to the Government of India.

We have the honor to be

Members of
Council.

We sincerely trust that the action of the Council will meet with the approbation of the entire Association, and that our friends on whose behalf the Council has moved will heartily appreciate their unanimous and energetic efforts to seek redress for their grievances.

We cordially congratulate the Association on the action it has taken, and we most sincerely hope that success will attend their appeal on behalf of our brethren in these services.

COMMENTS AND NEWS.

A DEATH-BLOW TO MIDWIVES IN ENGLAND.

WE have much pleasure in reproducing in *extenso* the following trenchant article from our estimable contemporary *The Medical Times and Hospital Gazette* of London:—"For some years past this journal has incessantly deprecated the custom, which has, unfortunately, become very widely extended, of the bestowal by qualified medical men, and even by respectable medical bodies, of diplomas in midwifery, to women who are possessed only of the most scanty knowledge and experience of the subject. Moreover, it has fallen within our knowledge that certainly some of these women were altogether destitute of personal character, and that therefore the individual or the society that testified to her professional standing, were bolstering up to the public a most undesirable and sometimes dangerous worker. In consequence of the stand which has been made by medical men on this matter, and notably by DR. RENTOUL, of Liverpool, the General Medical Council last May, it will be remembered, passed a resolution to the effect that such certificates were calculated to deceive the public. Nevertheless, the resolution of the Council was treated with marked contempt by the individuals and societies complained of, because they continued their irregular practices. Now, we are glad to see that the General Medical Council has vindicated its position, and has passed the following resolution upon the advice of its eminent legal advisers.

"(a) That the Council, being of opinion that certain documents issued by various societies or persons as diplomas of education and examination in midwifery are 'colorable imitations' of diplomas conferring a legal right to admission to the Medical Register, and both contravene the spirit of the Medical Acts, and are calculated to deceive the public, hereby give notice that from the present date the issue of such 'colorable imitations' by registered practitioners will be regarded as conduct infamous in a professional respect.

"(b) That in the opinion of the Council, the form of the certificate now before the Council, and purporting to be granted by the Obstetrical Society of London on 20th, July 1894, is such that it may be regarded as a document coming within the purview of the foregoing resolution. And that this opinion be communicated to the President and Council of the Obstetrical Society.

"Probably, never in the whole history of medicine has such a severe and well-deserved public censure been passed upon any medical society, and the present President and Council of the Obstetrical Society of London must surely feel much humiliated. The protests which have been made for years by their medical brethren against the deceptive documents which they have issued to midwives, have passed over their heads unheeded and uncared for; and for the severe condemnation which they have now received from the Parliament of their profession they have therefore only themselves to thank. They may be able—we hope they will—to escape from the awkward position in which they now stand. But it will never be forgotten against them that, in the opinion of the General Medical Council, the President and Council of the Obstetrical Society of London have contravened the spirit of the Medical Acts, have issued documents calculated to deceive the public, and have therefore been guilty of conduct infamous in a professional respect.

"The matter will certainly not rest here, and we presume, therefore, that the President and his colleagues will immediately cease to issue their so-called 'diplomas.' They would be well advised if they immediately and altogether discontinued their midwifery examinations, because the general practitioners of the kingdom will certainly question the

validity of any future certificate which they may issue. We take it for granted therefore that what is termed 'the diploma of the London Obstetrical Society' will now disappear into the limbo of forgotten and discredited things.

"A very considerable blow has therefore been given to the utterly shameful traffic which has been going on in pseudo-midwifery certificates for the last few years, and coincidentally to the pretensions of midwives, after a three months' educational training, to be placed upon the same footing as medical men who have to pass through five years' arduous and expensive training. In these columns we have frequently asserted our belief that midwives are doomed to extinction, and that in the near future they will cease to exist. We have been steadfastly opposing, on behalf not only of general practitioners but also of the public, the proposed legislation for midwives, and we deeply regret that in the professional press we have had, with the exception of the *Provincial Medical Journal* and the *Nursing Record*, to stand almost alone in this matter, the *Lancet* and *British Medical Journal* unfortunately wielding their influence in favor of galvanising into fresh life an altogether obsolete class of workers. Our contemporaries have had their reward, and we are pleased to know that we are receiving ours, because our view of the primary duty of a medical journal is to protect the interests and to expound the views of those whom it has the honor to represent in the public press. We will revert to this matter again, but at the present moment take this opportunity of assuring those whom it may concern that with patient perseverance we shall continue our efforts until the midwife has disappeared from the land, and efficient and well-trained workers have taken her place. We beg to assure the gentlemen who are giving colorable imitations of medical diplomas, conferring a legal right to admission to the Medical Register, that we have in our possession a fairly correct list of their names, and that we have only been waiting for this definite pronouncement from the General Medical Council to take action in the matter. The Incorporated Medical Practitioners' Association, we are informed, will take the necessary measures to prevent any infraction of the Regulation now laid down by the General Medical Council, and we are therefore acting kindly towards those now declared to be guilty of "infamous conduct" in a professional sense in warning them immediately to discontinue the practices which have brought discredit upon themselves and so much harm to the public and their fellow-practitioners."

STRYCHNINE IN SNAKE-BITE.

DR. ELLIOT's paper on strychnine in snake-bite will be read with profound interest everywhere. Unquestionably it must be admitted that the experiments are marked by the greatest care, and are based upon sound scientific principles. The profession in India is under a debt of gratitude to DR. ELLIOT. The difficulties placed in the way of the mafasal practitioner of testing the clinical value of DR. MUELLER's method of treatment are insuperable. DR. ELLIOT insists upon certain indubitable proofs being offered before the strychnine cure can have any reasonable pronouncement of opinion made upon it. We would draw special attention to these points; for without substantial proof of these clinical requirements, all reports of cases of snake-bite will hence forward be received with considerable dubiousness. DR. ELLIOT approached his subject with a prejudice in favor of strychnine, and no one will fail to recognize the honest spirit of his efforts and the honesty of his work and its results. To our mind, while we have always felt disposed to hope that a remedy for snake-bite had been found in DR. MUELLER's method by strychnine, we have had the ever present uncertainty that has forced itself upon our reason and judgment, that the most critical and important evidence as to the SNAKE

AND ITS BITE was shrouded with doubts or supported by the feeblest shreds that could never be accepted as "evidence of fact." Our readers and those who have reported cases of snake-bite must approach this vital subject without bias. If flimsy statements are set aside by "facts" clear as daylight, if a dozen doctors in a laboratory or ONE for a matter of that, can show us a cobra, strung and full of venom, a cobra and nothing but a cobra, and we see that cobra bite an animal and that animal dies from the bite without the aid or intervention of strychnine, and if that same reptile bites another animal immediately after its first victim and this animal is fully treated with strychnine and dies, we can only conclude after such an experiment has been repeated over and over again with similar results, that the drug used is ineffectual in saving life, and as it affects animals, is not an antidote to cobra poison. And we feel sure that the analogy that undoubtedly exists between the lower animals and man, makes the assumption reasonable that cobra poison will not find an antidote in strychnine when applied to the human organism. This is certainly the conclusion that forces itself upon our minds after studying DR. ELLIOT's experiments, and after reading the strong corroborative support given them by the physicians who witnessed his work.

There is just one point which we do not find borne out by DR. ELLIOT's experiments, viz., the comparative difference between the effects of cobra poison injected into an animal by syringe-dosage and by the natural method of snake-bite. What quantity of poison does a cobra impart to its victim? Is it more or less than an experimenter injects with a syringe? If it is less, then the experiments must be repeated and proof be forthcoming that the fatal dose of the snake-bitten animal was the test in every case by the injection method of poisoning.

THE ART OF VENTRILLOQUISM.

M. M. FLATAU and GUTZMANN rob ventriloquism of its sentimental phase by declaring that the illusion of the ventriloquist's voice coming from a different direction to that from which it actually issues is produced by variations of tone and of the resonant accessory cavity, and by the ventriloquist completing the illusion by gazing with an astonished or frightened look in the direction from which he wishes the sound to appear to come. The ABBE DE LA CHAPPELLE in 1772 A.D. declared that the stomach played no part in ventriloquism, which was the result, by habit, of a certain constriction of the throat. RICHERAND attributes this phenomenon to a lowered epiglottis and the scanty escape of air through the glottis, and LESPAGNON ascribed it to a very accentuated elevation of the velum of the palate; but while LISKONUS attributes ventriloquism to inspiration, MAGENDIE terms it a modification of natural sounds, MULLER claims it to be due to expiration through a contracted glottis, and GEOFROY DE SAINT-HILAIRE designates it as *engastrimythismus* produced by the aid of a second rudimentary larynx. FLATAU and GUTZMANN prove that the vibration of the larynx is very feeble, and while the abdominal muscles are stretched, the epigastrium and diaphragm remain in the position of inspiration, the epiglottis is forced backwards, so that the false cords and the cartilaginous portions of the glottis almost touch each other, and the pillars forming a very sharp angle the tension of the velum of the palate greatly increasing to lower the normal intonation a smaller quantity of air is thrown out than in ordinary speaking, and the voice assuming an octave higher than its natural tone so moderates the emitted sound as to make it appear to come from some other direction or person than from where it actually originates.

THE CAUSE OF ENTERIC FEVER AMONG EUROPEAN SOLDIERS.

In order to still further analyse the connection between the prevalence of enteric fever among our European soldiery in India, we have asked for the following information from the Sanitary Commissioner with the Government of India:—

(1.) Statement shewing the number of *European soldiers* attacked with enteric in 1891 and 1892 separately according to age as under—

| | 24 and under. | 25 to 29. | 30 to 34. | 35 and upwards. |
|-------|---------------|-----------|-----------|-----------------|
| 1891. | | | | |
| 1892. | | | | |

(2.) A similar statement for *officers* of the Army in India.

(3.) Statement shewing the number of cases of enteric among soldiers according to *RESIDENCE* in India as below.

| | 1st and 2nd years. | 3 to 5 years. | 6 to 10 years. | 11 and upwards. |
|-------|--------------------|---------------|----------------|-----------------|
| 1891. | | | | |
| 1892. | | | | |

(4.) Similar statement with regard to *officers*.

Statements of the above kind are not in the Sanitary Reports. Like statements are to be found for European soldiers with regard to *mortality* from enteric, but not with regard to cases admitted or attacked.

THE MARRIAGE OF SYPHILITICS.

DR. F. E. MAINE thinks that syphilitics ought *not* to be permitted to marry, as no matter how *apparently cured*, they cannot procreate a vigorous, healthy and noble type of manhood, and no benefit accrues by populating a nation with a weak-minded feeble-bodied humanity. He shows that syphilis may manifest itself at any time between four months and 24 years after the initial chancre, and declaring that so called anti-syphilitic treatment is a delusion, disputes the possibility of syphilitic parents bearing healthy children, and points out that if apparently healthy children born of syphilitic parents be watched to puberty and maturity their blunted intellects, early decay, and weakened bodies all tend to shew the truth of the Bible declaration of the sins of the parents being visited upon the children, even to the third and fourth generation.

THE ABOLITION OF THE C. D. ACT BY PARLIAMENT.

THE following resolution was passed by the British House of Commons, in June 1888:—

"That in the opinion of this House, any mere suspension of measures for the compulsory examination of women and for licensing and regulating prostitution in India, is insufficient, and the legislation which enjoins authorities or permits such measures ought to be repealed."

That legislation stands repealed to-day to the honor of England. May it stand repealed and the ACT be branded as an infamy for all ages.

THE NEED OF A SANITARY SERVICE FOR INDIA.

DR. W. J. SIMPSON's able and timely paper on the need of a sanitary service for India demands the most thoughtful perusal of all medical men and of the public generally. We trust his experience as a sanitary expert will carry considerable weight with the "powers that be," and that antiseptic and energetic action will be taken on the lines indicated by DR. SIMPSON.

His remarks on an outbreak of cholera in Dum-Dum are pregnant with caution to the military authorities, and it is to be hoped the incident so graphically described will arouse the needed enthusiasm to prevent preventable disease by measures that seem so simple and yet so effectual.

NEW MEMBERS OF THE INDIAN MEDICAL ASSOCIATION.

We have pleasure in publishing the names of the following gentlemen who have joined the Association since our last issue:—

John Robert Charles Hall, Asst. Surgeon, I. M. S., New Civil Lines, Lucknow.

B. D. Raghavendra Rao, L.M.S., Asst. Surgeon, Fort, Bangalore.

V. Abboy Naidu, L.M.S., Asst. Surgeon, Lunatic Asylum, Pettah, Bangalore.

V. S. Rajagopal Moodaliar, Hospital Assistant, Lunatic Asylum, Bangalore.

P. Palpu, L.M.S., Asst. Surgeon, Lunatic Asylum, Bangalore.

George Mannas, Hospital Assistant, St. John's Hill, Bangalore.

Robert George Ives, Asst. Surgeon, I. M. S., Station Hospital, Neemuch.

J. T. Parkinson, Asst. Surgeon, I. M. S., Presidency General Hospital, Calcutta.

Abdul Hafeez, Hakim, Hyderabad Medical School, Civil Dispensary, Koilkonda, *via* Janmupet (Deccan).

Medical men and women in all parts of India and Burma who desire to take a share in aiding the advancement of the Indian Medical Association are cordially requested to write to the Editor of the *Indian Medical Record*, and he will gladly send them blank membership forms and prospectuses. We are glad to find many willing volunteers.

SHORT ITEMS.

In accordance with the rule that Government must be consulted in the matter of fees to medical officers from Native Chiefs, sanction was recently accorded to the acceptance of a fee of Rs. 1,000 by Dr. Little, Civil Surgeon of Mooltan, for attendance on a recent occasion on the Nawab of Bahawalpur.

Dr. Elizabeth Bielby, Physician to the Lady Aitchison Hospital, Lahore, proceeds on long leave to Europe shortly.

Small-pox of a virulent type is raging in Gujranwala, Jhelum and Rawalpindi.

Miss Charlotte Ellaby, M. D., came out to India two months ago at the request of H. H. the Jam of Jamnagar, in order to perform an operation for cataract on his wife. We are glad to hear that the operations on both eyes have been entirely successful.

Speaking of the death of Father Denza, the late astronomer of the Vatican Observatory, the *British Medical Journal* says he was the foremost of the climatologists of our day, and that his researches on the origin of the Sirocco were a most solid gain to science.

Small-pox has appeared in Calcutta in a severer form than it has for some years. The weekly death-rate from this disease has gone up from 2 to 14 and 84, and several Europeans and Eurasians have been among the victims. Vaccination is being actively resorted to.

Sir John Tyler, Inspector-General of Prisons, takes three months' leave, beginning in the hot weather. Dr. Geoffrey Hall, Superintendent of the Naini Central Jail, will officiate for him.

Surgeon-Major Clarence Smith has submitted his memorial to the Secretary of State, praying that he may be publicly tried or reinstated into the I. M. S.

Dr. George King, F.R.S., Superintendent of the Botanical Gardens, Calcutta, has been granted two years' extension of service by the Secretary of State on the recommendation of the Government of India.

Assistant Surgeon C. E. Cornelius, I. M. S., Peshawar, met with a fatal trap accident on the night of the 18th January resulting in a fracture of the base of the skull. He died next morning. He was a very promising young officer.

It is rumoured that Surgeon-Colonel Robert Harvey, M.D., D.S.O., will succeed Surgeon Major-General Bradshaw as Surgeon-General of the British forces in India. Colonel Harvey has postponed his leave.

Dr. Ranjit Singh, L.M.S., a successful practitioner of Agra, was decoyed by ruffians into a village and murdered. Seven arrests have been made of alleged perpetrators of the deed.

Mr. Arthur R. C. Sanders, son of Surgeon Lieutenant-Colonel R. C. Sanders of Calcutta, was fifth on the list among the successful candidates for the Royal Military Academy at Woolwich.

Dr. Fatch Chand, M. B., B. S., L. L. Sc., L. R. C. P., Edin., L. S. A., London, late Civil Surgeon of Gujranwala, has launched into independent Private practice.

Current Medical Literature.

MEDICINE.

Whooping Cough.

At a lecture delivered at the Charing Cross Hospital, Dr. J. ABERCROMBIE divided this disease into *three* stages of symptoms:—The catarrhal, the spasmodic, and the period of convalescence. Fever is not necessarily present, but it may be in the second stage, and especially in lung complication. There are paroxysms of a hard, irritable cough (especially at night) but the hoop is not always present and babies, under six months old, who do not usually hoop turn red or blackish in the face after each paroxysm of coughing. There may be coryza, epistaxis, suffusion of the eyes, and sometimes the severity of the paroxysms produce hernia or bleeding from the mouth, nose, lungs, ears or into the conjunctive but hemorrhages into the skin are very rare. The duration may vary from one month to two or three months, but the infectiousness rarely six weeks after the onset of the illness and second attacks very rarely occur. Although the disease is highly infectious and very short contact is necessary, yet no special bacillus has yet been found and no explanation is forthcoming as to why the attack follows so closely on menses. Amongst its complications and sequelae are:—Collapse of the lungs or of part of the lungs, acute emphysema, bronchitis, catarrhal pneumonia, pleurisy, empyema, hemorrhages into the lung, brain or meninges convulsions, thrombosis of the sinuses, persistent vomiting leading to wasting, diarrhoea, epistaxis, hæmoptysis, sub-lingual ulceration, caseous glands, epilepsy, hemiplegia, sclerosis of the brain and acute tuberculosis as an ultimate sequel. The younger the child the graver the prognosis and every complication enhances the danger; but there are no *post-mortem* appearances peculiar to the disease. There is no special treatment necessary in slight cases, beyond strict hygiene, careful diet, expectorants and diaphoretics. Belladonna and ammonium bromide are invaluable for the paroxysms, but some prefer liq. atropine sulph. in half-drop doses to belladonna, and others recommend paregoric, and special medication should be directed towards any complication that may present; but change of air and cod liver oil work wonders in many cases.

Starting points of Tuberculous Disease in Children.

Dr. J. W. CARR divides tubercular infection into *three* classes, those in which (1) there was a definite lesion at the seat of infection, (2) there was no local lesion at point of infection and (3) those in which the constitutional infection developed later on; the local lesion being slight or healed as to starting points he distinguishes *five*:—(1) In the glands the liability being at its maximum in infancy and decreasing in later childhood. (2) Lesions in the cervical glands, as in the joints, may be due to infection by the blood, but caseation of the bronchial and mesenteric glands occurs from direct infection from the organ to which they are connected as bacilli pass through the lungs and intestinal walls and then enter *not* the blood vessels but the lymphatic channels. (3) Though infection occurs through the intestines, still tuberculous disease starts more frequently in the thorax than in the abdomen. (4) Caseation of internal glands is often unsuspected and impossible of diagnosis when associated with obscure febrile conditions. (5) Unhealthy mucous membranes and rickety conditions. He thinks that prophylaxis by increasing the resistive powers of the system against the access of bacilli is the wisest way of dealing with tubercular diathesis.

Subnormal Temperature of the Body.

JANSSEN finds that though the temperature may be normal in severe collapse, still very low temperatures may be found unaccompanied by any symptoms of collapse. He thinks that when subnormal temperatures persist in cachectic persons, the prognosis is generally unfavorable, and he attributes this fall of animal heat to nine sets of causes:—(1) Withdrawal by heat by exposure of the body to a very cold atmosphere or by immersion in very cold water. (2) After cholera, diarrhoea, profuse hæmorrhage, &c., where there is great loss of fluids from the body. (3) Diabetes, pernicious anemia, cancer in the alimentary canal and other conditions of cachexia and inanition, many chronic mental diseases and during convalescence from fevers. (4) Grave circulatory disturbances. (5) Diseases of the brain and central nervous system. (6) Intense irritation of sensory nerves and surgical shock. (7) Extensive burns and affections of the skin. (8) In the course of certain fevers as in pyæmia or the temperature may remain subnormal for a long time *after* fevers. (9) In diabetic coma, the auto-intoxication of uræmia, and in poisoning by alcohol, atropine, carbolic acid and morphine. He furthermore declares that subnormal temperatures are far more common than is generally supposed, and that depressions under 91.4°F (33°C) are by no means rare.

—:O:—

SURGERY.

The Treatment of Ophthalmia Neonatorum.

KALT recommends irrigation of the eye with a 1 to 5,000 solution of potassium permanganate introduced through a small funnel, one end of which is placed between the eyelids, and the other connected with the bottle containing the fluid, which should be placed about a foot above the patient's head. The irrigations should be made twice a day, and two quarts of the fluid should be used at each time. If the disease is attended with serious or extensive trophic changes in the cornea, the irrigations must be used more frequently, say four times a day, and gradually lessened as the inflammation disappears. At a recent meeting of the Ophthalmological Section of the New York Academy of Medicine, this plan of treatment was favorably commented on by Dr. H. KNAPP, who had seen its application by KALT.—*N. Y. Med. Jour.*

A New Method of Resecting the Rectum.

DR. ROUTIER described (Chirurgical Society, Paris) a method of resecting the rectum as devised by MOULONGUET, a modification of KRASKE'S operation. The first step is the same as in KRASKE'S operation; the sphincter is then dissected out, and even though the lower portion of the rectum is found healthy, it is cut away instead of being preserved, as in KRASKE'S operation. The sphincter, after having been dissected out, is lined by the upper portion of the rectum, which is pulled down for this purpose and sutured to the edges of the wound at the anus. The perineosacral wound is then sown up, with a drain in the lower portion. In DR. ROUTIER'S estimation the usefulness of the operation is rather limited, especially to cases in which the cancer is not situated high up, and in cases in which the sphincter is intact.—N. I. Med. Rec.

Trephining for Head Injuries.

MYNTER in the inside of two years trephined 27 cases: 15 for fracture of the skull, all recovered except 4, in whom there was extensive fracture of the base; 5 for traumatic epilepsy, of the 4 who were greatly improved one began to get fits some six years after the injury to his skull and gradually got worse, until he was trephined, after which he rapidly recovered and returned to his work for 17 months, when the fits returning as bad as ever he was again trephined, and after six months' absolute rest left hospital apparently cured. In 5 cases for microcephalus with idiocy there was no improvement. One case of subdural hæmorrhage with aphasia and hemiplegia was completely restored to health, and one case of abscess of the brain in which there was very rapid recovery.

Novel Treatment of Oblique simple Fracture of the Leg.

AFTER freely exposing the seat of fracture and bringing surfaces into accurate apposition, MR. A. LANE drills holes through the broken tuba and firmly secures the fractured parts in position by means of plated steel screws in which the thread runs right up to the head. This treatment not only shortens the period of recovery by compelling union by first intention without pus formation, but also immediately relieves pain by the absence of tension and extravasation of blood into the tissues, as well as prevents the deviation of the axes of the lower fragments of the broken bone from their original dissection and the sense of insecurity in and pain of the joints brought about by that deviation.

Laminectomy for Spinal Fracture.

WHILE he admits that damage to the cord occurs the moment that any vertebra is broken and that the possibility of restoring function and limiting secondary sequela rapidly decreases with time, ROBERTS advocates operation under antiseptic conditions, and suggests an exploratory incision whenever doubt arises as to the existence and location of spinal fracture, as prompt removal of the pressure on the cord holds out the only chance for restoration of its function, and though the damage to the nervous system may often be irreparable, still laminectomy gives the patient a chance which, justifies the risks from hæmorrhage and the shock of the injury as also of the operation by removing the immediate danger to life.

OBSTETRICS AND GYNECOLOGY.

Sepsis Puerperalis.

GOLDSCHNEIDER follows KEHRER'S classification: (1) *Sepsæmia*, a febrile state due to resorption of putrid masses from the cavum uteri. This fever, which subsides after thorough local antiseptic treatment, shows peculiar features: intermittent or markedly remittent, initial chills, full pulse

but of moderate tension, respiration 40 per minute, stinking lochia and sometimes herpes labialis. (2) *Peritonitis puerperalis*, in which the temperature may rise from 38° to 42°C, and the abdominal tenderness is characteristic of peritonitis. (3) *Puerperal pyæmia, thrombophlebitis, septic pyæmia*, in which the prognosis is better than in the septic form, fever pulse full and bounding, stinking lochia, repeated chills, embolism, pus or pyogenic products circulating through the blood, and sometimes diphtheritic endometritis and diphtheritic puerperal abscesses. (4) *Septicæmia*, which varies according to the malignancy and number of the invading streptococci. The lines for treatment are:—Local therapy in sepsæmia, but no local treatment in the other forms of puerperal fever, except gentle irrigation in endometritis purulenta. Abundant nourishment, alcohol, absolute rest and sleep, active stimulation and tincture strophanthus in cardiac weakness.

Vaginal Hysterectomy by Enucleation without Ligature or Clamp.

TO SAUTER is due the honor of being the first (A. D. 1820) to perform this operation, which is described in CHELUS "System of Surgery," published 1847, but no one seemed to care to follow suit till very recently, when PRATT of Chicago revived it, and on 12th October 1894 it was performed for the first time at New York, U.S.A., by DR. J. R. GOFFE. The subject was an Irish woman *æt.* 46, suffering for 7 years with complete procidentia uteri and its train of torture. Asepsis having been established, a circular incision was carried round the cervix through the vaginal wall with a scalpel, and the tissues pushed away with the handle of the knife. Adhering closely to the uterus, he dissected away the tissues with a THOMAS'S spoon saw till he reached the peritoneum in DOUGLAS'S pouch, which he first snipped with the scissors and then tearing it right and left with his fingers continued the dissection with the spoon saw till he separated the bladder from the uterus and saw the cornua of the latter sustained by nothing except the round ligaments, which he transfixed by passing a single strand of braided silk (high up) through the upper part of each broad ligament and then delivered the uterus by cutting away the round ligament at either horn. The peritoneal surfaces having been brought in contact with each other by strong catgut sutures and occluded the upper end of the vagina by turning all raw tissue into it and bringing down and firmly securing the broad ligaments to its upper part by means of silk sutures, a light packing of iodoform gauze completed the operation, which took a few seconds less than half an hour. There was little or no after-hæmorrhage, and the patient's recovery was uninterrupted.

The Care of Pregnant Women.

DR. DEWEES of Salina holds that the true source of suffering during gestation and child-birth is found in the carelessness or ignorance of civilisation with its fixed habits of excesses which women should be taught to resist by cultivating the self-discipline necessary to enable them to prevent the continuous irritation from excesses in life habits, as impure sensual indulgences, indiscriminate excesses, improper posture, food, dress and drink and erroneous habits of living all conduce to the diseases peculiar to pregnancy and parturition, and which are largely preventible by correction or removal of these errors. He also insists on the necessity for the physician to ascertain whether the patient be really pregnant and whether the pregnancy be uterine and normal or abdominal, tubal or abnormal. He should keep a record of the temperature, make repeated examinations of the urine, and carefully note the age, history, parity, environments, general health, habits and station of life, dress, food, drink and period of gestation.

Symphysiotomy in Private Practice.

WALLICH called in to a multipara in her fifth labor, which was proceeding very slowly—the dilatation being about the size of a 5 franc piece only, after 55 hours of travail. When the membrane ruptured, the amniotic fluid was greenish and the head, which was still above the brim, showed no tendency to descend, although at the end of 72 hours the pains were still vigorous and the fluids had been already discharged 7 hours. Forceps proving of no help, the patient was placed on a chest of drawers in the obstetrical posture, anaesthetised, and symphysiotomy performed under antiseptic precaution. The cartilage and sub-pubic ligament being divided, the pubic bones were separated for 5.5 cm, and after the extraction of a living child weighing 3810 grammes and the placenta, the pubic bones were approximated, the uterus was washed out, the wound sutured and the pelvis was bound up with a plaster-of-paris bandage. On the eighth day the deep stitches were removed, the superficial on the following day, the plaster-of-paris belt on the 13th, and on the 20th day the patient moved about without any pain. The following measurements were taken of the foetal head which refused to pass through a sacro-subpubic space of 10.7 c.m. diameter: Biparietal 9.4 c.m., bitemporal 18.2, sub-occipitobregmatic 9.9, suboccipito frontal 11.6, occipito frontal 12.1 and occipito mental 11.6.

The Management of Abortion.

DR. E. J. ILL points out that as abortion is a pathological and not a physiological condition, as is birth at full term, it becomes a duty if there be any certainty that the product of conception will be cast off, to at once relieve the patient instead of letting her run the risks pertaining to retained secundines. Hot vaginal douches and hot rectal injection considerably assist the uterus in its work of emptying itself slowly of the intact ovum and occasionally dilatation of the os externum with Goodell's dilator gives satisfactory results. When the ovum is intact, the uterus forces it out into the cervical canal from whence it can easily be removed by a sweeping motion of the finger. If there be severe hemorrhage, place patient on her back with hips over the lower end of a table, cleanse vagina and cervix thoroughly, introduce a Sim's speculum through which push a long narrow strip of gauze into the uterus till the cavity is completely filled up, and securely plug the vagina round the cervix and os. In those cases where the uterus will not do its own work of expulsion pass two fingers of the right hand, per vaginam, anterior or posterior to the cervix, according as there may be an antroversion or a retroversion, and with the left hand press the uterus from the abdomen down on to the right hand fingers until the ovum is broken and a finger passes into the uterine cavity, when thoroughly wash the vagina and vulva with soap and hot water, irrigate with 1 in 4000 bichloride solution, anaesthetise the patient, place her in lithotomy position, introduce a Sim's speculum through which grip the anterior lip of the cervix, so as to straighten the canal, and after widely dilating the canal with an Ehlinger or a Goodell dilator thoroughly curette the uterine cavity with a sharp instrument, taking care to completely remove the entire endometrium, and paying special attention to the horns and fundus which are the most difficult parts to clean. Thoroughly irrigate the uterus and vagina with bichloride solution, and after careful examination that nothing is left behind of the products of conception, mop out the vagina and loosely pack it with gauze. Serious consequences never follow this operation when carefully performed.

PHYSIOLOGY, PATHOLOGY AND BACTERIOLOGY.

The Inoculability of Cancer.

DR. GRATIA reported, at the Academy of Medicine, Brussels, a series of experiments, in which he had employed grafting and inoculation, with the object of proving or disproving the inoculability of cancer. The result of his experiments led him to conclude that cancer does not seem to be inoculable even between individuals of the same species. He likewise feels justified in making the following statements: 1. The parasitic nature of cancer has not been satisfactorily proved. 2. The direct or indirect contagiousness of this neoplasm has not been proved; the most that can be admitted, in the present state of our knowledge on this subject, being the possibility of ingrafting, that is to say, transplanting cancer, and that only in individuals exhibiting exceptional predisposition, such as cancerous patients themselves. 3. The etiology and pathogenesis of cancer are still undetermined.—*N. Y. Med. Rec.*

Vitality of the Typhoid Bacillus.

ACCORDING TO UFFELMANN (*Centralbl. f. Bakt.*) typhoid bacilli resist drying for a long time. From his investigations he concludes that these micro-organisms retain their vitality in a dry state for many days,—in ordinary earth, twenty-one days; in street sweepings, thirty days; or more in sand, eighty-two days; on wood, thirty-two days; and on linen over sixty days. In moist media it is very probable that the microbes would retain their power of growth still longer. The same investigator proves that typhoid bacilli may be carried by the air as well as by the clothing, and that they are thus capable of infecting milk, water, and various food stuffs.

UFFELMANN's mode of distinguishing the typhoid bacillus may be briefly stated as follows: In the microscopical examination, low powers, not exceeding 100 diameters, are employed. A careful note is taken of the movements of the microbes and the shape of the colonies as compared with typical colonies. The fact that typhoid bacilli do not induce fermentation in 2 per cent. lactose gelatin is also utilised, together with the characteristic growth upon methyl violet gelatin.—*Modern Med.*

Staphylococci and Acute Rheumatism.

SACAZE points out that in many cases of acute articular rheumatism it is possible to find, or obtain a history of some lesion which may allow these organisms to pass into the circulation. This lesion may be some injury or an acute tonsillitis of marked severity. He brings forward several cases in support of his theory, and also quotes the researches of SAINT-GERMAIN, who found joint effusion as the result of the intravenous injection of cultures of staphylococci of feeble virulence. In the fluid in these cases no organisms were found, as is frequently the case in acute rheumatism. On the other hand, BOUCHARD and CHAMAIN are quoted as having found large numbers of staphylococci in the serous effusion from the joints of patients suffering from rheumatism.—*B. M. J.*

Rapid Detection of the Typhoid Bacillus.

LYONNET gives the following:—An ordinary culture bouillon is taken and decolorised with animal black, and 1 per cent. of phenic acid and 20 per cent. of lactose is added, with a small quantity of Congo red. Owing to the phenic acid only the typhoid bacillus and bacterium coli are able to grow in it. If the typhoid bacillus be present, the milk sugar does not ferment; the bouillon becomes cloudy but remains red. If the coli bacillus be present, the bouillon becomes cloudy, the milk sugar undergoes fermentation, and lactic acid is formed, which changes the color of the bouillon from red to violet. Hence, if the broth remains clear, neither the typhoid nor coli bacillus is present. If the broth becomes turbid but remains red, it is probably due to the presence of the typhoid bacillus. Lastly, if the broth becomes turbid but at the same time is changed to a violet color, the presence of the coli bacillus may be inferred.—*San. Med.*

PUBLIC AND DOMESTIC HYGIENE AND JURISPRUDENCE.

The Prevention of Smells by a Film.

AN interesting observation on this subject has been brought to our notice by a correspondent. It consists in the fact that when a few drops (three) of eucalyptus oil are thrown upon the surface of the water in the pan of a water-closet before it is used, the smell of the faeces subsequently added is prevented from escaping. This seems to be due to the formation of a film of oil over the surface of the water and, of the faeces, so that the emanation of objectionable smells is prevented. Oil of eucalyptus would appear to be unique in the possession of this property, since other oils, used with a view of reducing what is to many the nauseating smell of eucalyptus, failed to effect the same result. This point is, however, receiving further investigation at the hands of Mr. J. FRETCHER, F.R.S.; but in the meantime we confess to being a little incredulous as to whether this method would serve as an effectual preventive of disagreeable smells arising when faecal matter is undergoing decomposition and when foul gases are being disengaged in visible bubbles.—*Lancet*.

The Use and Abuse of Toothpicks.

THE exciting causes of caries of the teeth are invariably external, and among these decomposition of food or of mucus between the teeth holds a prominent place. It follows that removal of such matter must be beneficial. One of the means of accomplishing this is the toothpick, which, judiciously used, is of undoubted value. Fool lodges between the teeth from a variety of causes: the extraction of a tooth may lead to those contiguous falling apart and so leaving spaces; improperly filled teeth, such as those left with rough edges or not sufficiently "contoured"—that is, built up to the original configuration of the lost part—will form fool traps; irregular position of the teeth or recession of the gums—all these will act in the same way. Attention to the dental toilet before company is certainly inelegant, but it is not necessary here to approach the subject except from a medical point of view. Of the materials used as toothpicks, the best is the quill with the sharp point removed, but with this, as with all other forms, care must be observed. By indiscriminate application the gums may be so irritated and injured as to cause recession and thus increase the existing trouble, or inflammation of the tooth membrane may be caused, a most annoying condition, and one in which the still more vigorous use of the toothpick gives temporary relief, only in reality to add fuel to the fire. Metal toothpicks are good because blunt-pointed, but are too thick to pass between teeth at all close together. Wood need only be mentioned to be condemned, for it is a by no means uncommon occurrence for small fibres to become detached and jammed between the socket and tooth, leading to chronic periostitis and even loss of the tooth if the condition is not recognised. An excellent substitute for the toothpick—one having few objections, and one which will save many a visit to the dental surgeon—is antiseptic, waxed, dental floss silk, which, passed between the teeth night and morning, will invariably reveal accumulations which have escaped the tooth brush, however carefully employed.—*B. M. J.*

The Feeding of Infants.

BEIDERT corroborates HEUBNER's bacteriological considerations of infant feeding by advocating the sterilisation of milk by boiling and subsequently cooling in a Soxhlet's apparatus, as cow casein is difficult of digestion and the undigested remains afford a soil for the growth of the micro-organisms that are formed in the saliva, stomach and intestines; and intestinal antiseptics chiefly depends on proper digestion and absorption of the intestinal contents. He observes that, though children appear to thrive

on breast-milk, they may yet have thin diarrhoeal stools which sometimes contain mucus, but this is not the case with those fed on cow's milk. In his opinion cream ought to be added to the milk to make it more digestible. He regrets that Loeffler's half-peptonised milk, which nearly approaches to human milk, cannot be effectually sterilised, and shows that the casein obtained from woman's milk chemically differs from that got from cow's milk.

A Dental Surgeon's Fees.

LAST week a dental surgeon successfully sued a lady patient for twenty-three guineas, the amount of his fees for the insertion of artificial dentures, including several visits required in the preparation of the mouth. It appears that the patient wrote expressing her satisfaction with the work, but subsequently returned the lower case, demanding back her old one, which had cost twelve guineas, but which had been broken up by the dentist and for which £1 had been allowed, together with a letter couched in such terms that Mr. PENFOLD, the plaintiff although expressing his willingness to make any requisite alterations, declined to do so unless an apology were offered. The defence took the usual form as to the value of the material used in the construction of the teeth. The plaintiff's case was to the effect that this had nothing whatever to do with the fee charged, any more than it would with a surgeon, say, in a case where splints were required. It is entirely a matter of skill and experience, and any reputable dental surgeon, whether the fee be a large or a small one, would not take this into consideration, either with regard to stoppings or mechanical work and so on. Now, apart from this particular case, there is something to be said for each of these views. Were the latter carried out by all dentists—that is, were no regard to expense taken—one of two things must happen: either the large body of practitioners would become bankrupt or the poorer classes would be practically debarred from dental services, for hospitals could not possibly supply the want, they having to consider ways and means; but undoubtedly those dental surgeons who are fortunate enough to command good fees should not, and we believe do not, base them according to whether gold or vulcanite is used for an artificial set, or gold or a plastic material for a stopping. As the judge justly remarked: "If a woman will go to a West-end dentist where big prices are charged, she must pay for it. If she had gone to other dentists she might have got the set for 20s."; but he did not suggest that the two were of equal value.—*Lancet*.

THERAPEUTICS AND PHARMACOLOGY

Diphtheria Antitoxin.

HANSEMANN denies that antitoxic serum has either prophylactic immune or curative powers, and submits cases where the serum has failed to cure and where it has set up secondary and dangerous inflammations. He contends that the cures obtained in the lower animals by antitoxic serum were cures not of diphtheria but of the "disease caused by Loeffler's bacillus," and shows that the hospital mortality for diphtheria was necessarily longer than in private practice, because only the most severe cases need to be sent to hospital. KICHOW, on the other hand, maintains that antitoxin has high therapeutic value, and holds that it is the duty of every medical practitioner to employ this remedy in diphtheria. BEHRING supports this latter view strongly and KLEIN, who thinks that ROUX's plan of preparing the serum is not only too tardy and tedious, but also difficult of acceptance from a theoretical point, contends that while 1 gramme of the twenty-three or of the twenty-six days' horse serum was capable of protecting from 20,000 to 40,000 grammes body-weight of guinea pig against the living bacilli and toxin of

diphtheria, 5 to 6 or 10 c.c. of this serum injected into the human subject gave highly satisfactory results in which the further spread of the membrane was entirely arrested and the existing membrane rapidly loosened and discharged. KLEIN works on the hypothesis propagated by the researches of BEHRING, KITASATO, PROFFER, WASSERMANN and others that the blood of an animal that has acquired immunity possesses antitoxic properties, whose degree standing in direct relation to the degree of resistance acquired by the animal furnishing it not only renders that particular animal capable of overcoming the disease in question, but also other animals into which its blood or serum is introduced. After giving a horse a few injections of attenuated living bacilli together with their toxin, he repeatedly injects into the same animal large quantities of living diphtheria bacilli (*minus* their toxin) taken from the surface of solid cultures of gradually increasing virulence. Every such injection is followed by a slight rise of temperature and a local tumour without suppuration at the point of inoculation. As soon as one tumour disappears a new injection is made, with large quantities of living bacilli scraped from the surface of solid agar and gelatine media, so as to allow the bacilli to grow, multiply, and by the end of the third week gradually produce within the body of the horse, first the toxin and ultimately the valuable antitoxin, and if after the first bleeding the horse be again twice or thrice injected with virulent living bacilli from surface cultures, the further serum from such horse will possess even increased antitoxic power.

Treatment of Alcoholism by Strychnine Nitrate.

BREED concludes a paper in the *Medical News* on this subject as follows:—

1. That we have in this drug a remedy that actually, for a period as yet undetermined, removes the desire for alcoholic stimulation in the chronic inebriate, and that without the least effort on his part.

2. A remedy that removes the distress and gnawing at the epigastrium, so common upon the withdrawal of alcohol.

3. A remedy that tones up the nervous system, allays the insomnia, the flighty and other bad feelings in the head, the mental disturbances, and the tremulous agitation and uncertainty of voluntary motions due to the withdrawal of stimulants.

4. A remedy that brings back the appetite and general physical vigor of the body.

5. A remedy that temporarily transforms a wholly demoralised creature into a man.

6. A remedy that is of great value in acute attacks of alcoholism.

7. Incidentally, a remedy that is an exceedingly good and safe heart-tonic.

8. More than all, a remedy that exerts a moral influence upon the patient, giving him what he had before wholly lost,—to wit, hope, enthusiasm, self-confidence, and courage, where before was despondency, abandonment, and despair; a steady, straightforward gaze, and a bright, youthful expression of the eye, which replaces the shamefaced, sneaking, apologetic air of total depravity of the chronic inebriate.

9. We have in the nitrate of strychnine not a remedy that will oblige a man to abstain from drink if he does not want to do so, and such subjects do not deserve one. From the results obtained by the gold cure, the silverash cure, the Kelsey cure, etc., we may conclude that we have a remedy that is as efficient as any of these and much safer; a remedy, moreover, that is not secret, and can be used by men who know the action of drugs and can use them with discretion and safety to the patient.—*Gallard's Med. Jour.*

Oil Injections in Dry Pleurisy.

DR. CERENVILLE of Lausanne, in obstinate cases of dry pleurisy, injects about thirty drops of olive oil, previously sterilised, with the object of imitating nature in providing a lubricating fluid. This very small quantity of oil appears to be sufficient for the purpose, as it is very diffusible and rapidly spreads over a very large part of the surface of the lung. With care and practice it is not difficult, he says, to find the right depth to insert the needle so as to penetrate into the pleural cavity without wounding the substance of the lung. He has up to the present time employed this little operation in ten cases which had resisted the ordinary methods of treatment by external stimulating applications, &c. In two of them only was no beneficial result observed, in six a marked improvement in the pain took place within a few hours, while in the remaining two cases a complete and lasting cure was obtained. It is obvious that this plan may conceivably be useful in pericarditis troubles; indeed, DR. CERENVILLE has employed it already in one case of the kind. Of course, he does not recommend that in every case of dry pleurisy olive oil should be injected, but he brings his plan before the profession as one that may fairly be tried in obstinate and painful cases when other and more ordinary means have failed. The site which should be chosen for the insertion of the needle is the spot where the friction sounds are the most distinctly heard.

Vomiting of Pregnancy.

DR. GOODALL recommends:—

| | | | |
|--------------|-----|-----|---------|
| Cerii Oxulat | ... | ... | gr. i |
| Ipecacuanhae | ... | ... | gr. i |
| Creasoti | ... | ... | gtt. ij |

M. Sig.—To be taken every hour until nausea is controlled.

Pruritus.

| | | | |
|------------------------|-----|-----|-----------|
| R. Liq. ammon. acetat. | ... | ... | ℥ij |
| Acid. hydrocyan. dil. | ... | ... | ℥j. |
| Sp. rectificat. | ... | ... | ℥ij. |
| Aq. rose | ... | ... | ℥viij.—M. |

—*Universal Medical Journal.*

Filaria Sanguinis

in chyluria may be driven out of the system by thymol gr. j. every four hours, with subsequent doubling of the dose.—*Bull. gen. de Ther.*

Gastralgia.

A formula emanating from Dr. Monin is:—

| | | | |
|--------------------|-----|-----|---------|
| R. Tinct. conif. | ... | ... | ℥j |
| Tinct. valerianae. | ... | ... | ... |
| Tinct. opii camph. | ... | ... | ... |
| Aq. laurocerasi | ... | ... | ss ℥ij. |

M. Sig.: Seven drops in a little milk when the pain appears.—*Prescription (U.S.)*

Menthol in Pruritis.

DR. COLOMBINI uses menthol in alcohol or in oil of almonds, or incorporated with ointments, for the relief of itching affections of the skin and mucous membranes. From three to five per cent is said to be one of the best remedies for this troublesome disease.

Hæmoptysis.

RECTAL injections of chloral, 1·5 to 2·5 grammes (24 to 38 minims), repeating dose if necessary. Effect apparent in one-half or three-fourths of an hour. Apparently acts as prophylactic. Fifteen cases successfully treated. First ascertain if heart be healthy.—(*J. PAL, Univ. Med. Jour.*)

Correspondence.

TEETOTALISM AND ENTERIC FEVER.
TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—At the Indian Medical Congress held in Calcutta during Christmas week, Surgeon-Captain FREYER, M.S., read a paper on "Teetotalism and Enteric." On the 22nd November 1894 the *Civil and Military Gazette* had published a leader under the same heading which was fully replied to by me in a letter published in its issue of the 7th December. DR. FREYER in his paper attempted to connect the liability to enteric fever with the habit of *temperance*, though as to in what manner this association came about he did not furnish any information. He merely related how the teetotalers in the Royal Irish Fusiliers at Allahabad and the 18th Hussars at Umballa, during a certain short period, had larger number of admissions for this disease than non-abstainers. But as I pointed out in the discussion that followed, and which appeared to meet the approval of the meeting, these figures were far too few and limited to afford any ground for conclusions one way or the other, and it was unjustifiable trying to generalise from one or two particular instances and attempting to unsettle the minds of temperance men. On common sense grounds, moreover, it is erroneous to even suspect that teetotalers would be more prone to a disease which primarily attacks the bowels, while the non-abstainer who not only "runs himself down," and thus reduces his vital powers, but indulges in an irritant (more or less diluted) which has peculiar, almost selective properties on the very parts of the internal organs specially affected by the disease, goes scot free. It does not stand to reason. The pertinent question may also be asked—Why is it that enteric is so common among officers, very few of whom are total abstainers?

DR. FREYER and other Army doctors, including Surgeon-Major DAVIES, late Professor of Hygiene, Netley, very properly condemned the barrack filters—and here probably lurks one of the main causes of this dread malady. DR. EARNEST HART, the Editor of the influential *British Medical Journal*, (an honored delegate to the Congress) afterwards joined in publicly condemning the Macnamara filter as the very worst one in use. I also added my humble voice to the general outcry for pure water, and pointed out how in the Central Jail (population 1,000) at Midnapore, of which, I am medical officer, severe epidemics of bowel disorder occurred periodically, and in 1893 the mortality rose very high (60 per 1000), but that since, among other things, the water had been really and thoroughly *boiled* and then properly filtered through wood charcoal and burnt brick (carefully attended to and changed fortnightly) our sickness and deaths had diminished wonderfully. And this is what I would urge on the military authorities. Use for every barrack a LARMORE'S guarantee boiler—fit up a simple masonry filter and reservoir—and then see if you do not defy the cholera, typhoid, and fever germs more than you do now.

Of course there are other things that also need attention: there is the milk and butter supply, the pure feeding and watering of cows, the purifying of the *goualas*, dairies, &c.; the heavily manured cantonment grass farms, and night-soil grounds, which poison the air and

subsoil, and of course the water passing them into our wells; and there are the *dhobies* washing clothing in foul pools, and so on. But let us first take care of our drinks—avoid bazar aerated waters, ginger-pops, and sherbuts and *boil our water and our milk*.

But even against old odds "the" temperance man must come off first best. SIR JOSEPH FAYEE, I. M. S., the great Surgeon at the India Office, says that "the young man who, coming out of India, neither smokes nor drinks is doubly armed against sickness and all other evils."

Yours, &c., P. W. O'GORMAN, Surgeon-Captain, I.M.S.,
Civil Surgeon, Midnapore.

MIDNAPORE, 24th January 1895.

CARBOLIC ACID FOR CARBUNCLE.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—He is a bold man who ventures to say of a thing like carbolic acid that it was *first* applied in any disease within the last few years. Surprised to see DR. WALLACE'S note with regard to its *first* use in carbuncle, I looked up NEALE'S Medical Digest and find that SIR PETER EADE used it in 1869. I myself have tried it for 10 or 12 years, either the pure acid, or in combination with iodine. For 6 or 8 years I have used it as follows: filling a hypodermic syringe with the liquified acid, I inject it at five or six places just at the margin, with pressure so as to force the acid into the interstices of the areolar tissue; in this way the spreading of inflammation seems arrested and the constitutional symptoms remit. I had thought this method original; but find from the Digest that this was also practised and written about 20 years ago.

Anyhow, the method is one to be recommended. There is more to be said in favor of complete excision than DR. WALLACE'S article would seem to admit. It is suited for the robust and secures more rapid healing than any other plan. The method consists in cutting outside any infiltrated tissue, down to the muscular aponeurosis underlying it. Special care should be taken to work from above downward, gripping the edge of the carbuncle as it is excised firmly with a vulsellum forceps, and dragging it out and down, so that none of the discharge should come in contact with the fresh surface. Corrosive sublimate irrigation should be continued the whole time. No attempt should be made to draw the edges together.

In two or three days skin grafts may be applied; and by combined excision and grafting the time required for healing is shortened to almost half that of other methods.

I do not recommend this procedure in the aged, or the weakly, nor in cases where a well-defined slough is already visible. It is in the differentiation of cases, and adaptation of various methods that experience comes into play. I think carbuncle in Kashmir is specially severe. A slough 4 or 6 inches in diameter is not rare, and I have seen it over a foot.

Yours, &c., ARTHUR NEVE, F.R.C.S.

KASHMIR.

INDIAN VITAL STATISTICS.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—I shall feel highly obliged by being furnished with information regarding the following points on "Vital Statistics"—

1. The average life of the Indians.
2. The highest number of years of their longevity.
3. Percentage death-rate at the age of 30, 40, 50, 55, 60, 70, 80 and 90 years.

Yours, &c., R. M. MAHAJAN, H.A.,
In charge Rajkot Dispensary, Katiawar.

RAJPOOTANA, 15th Feb. 1895.

REVIEWS.

A MANUAL OF HUMAN PHYSIOLOGY: PREPARED WITH SPECIAL REFERENCE TO STUDENTS OF MEDICINE. By Joseph H. Raymond, A.M., M.D., Professor of Physiology and Hygiene in the Long Island College Hospital, and Director of Physiology in the Hoesland Laboratory. (Publisher: W. B. SAUNDERS, Philadelphia.) Price \$ 1.52.

The work before us is divided into four principal sections, viz., (1) Physiological Chemistry, (2) Nutritive functions, (3) Nervous functions, and (4) the Reproductive functions. In the 366 pages of beautifully clear, large and easily readable letter-press, DR. RAYMOND has packed away an immense amount of information, useful to the student of medicine, and to the busy practitioner.

Bearing, as the work does, a special reference to the study of medicine, only the main facts and principles of the great subject of physiology, which lie at the very foundation of a sound knowledge of the healing art, are given, relegating the more recondite and obtruse parts of the subject to larger text-books. As a practical work then, DR. RAYMOND'S "Manual of Human Physiology" should go hand in hand and *pari passu* with every clinical and practical work on medicine and surgery. Under the heading "*Nutritive functions*," such subjects as digestion, absorption, respiration, vital heat, circulation, lymphatics, ductless glands, skin and kidneys are very fully and accurately considered. The brain and nervous system also receive a large share of attention.

The Senses of Sight and Hearing are treated in a very full, able and "assimilable" manner, that is to say the facts are put in such a terse way as to be easily grasped and "assimilated" by the student and retained for future reference.

The closing chapters are devoted to reproduction and development.

DR. RAYMOND is to be congratulated upon the production of a treatise on *The Institutes of Medicine*, at once practical and clinically useful, in that it contains all that can be said on the subject "in a nut-shell" as it were,—in that it is accurate and up-to-date, and that it can be used along with any published work on medicine or surgery to throw further light upon and elucidate those subjects.

THE CARLSBAD TREATMENT FOR TROPICAL AILMENTS AND HOW TO CARRY IT OUT IN INDIA. By Louis Tarleton Young, M.D., B.Ch., B.A., Medical Travelling Prizeman (University Dublin). Formerly Professor of Materia Medica and Chemistry in the Lahore Medical College, and 2nd Physician to the Mayo Hospital, Lahore; Fellow and Examiner, Punjab University; Civil Surgeon, Umballa; Surgeon-Major, H. M's. Indian Army. (Publisher: Thacker, Spink & Co., Calcutta.)

This splendid monograph on the Carlsbad Treatment of Tropical Ailments stands quite unique, consisting as it does of 9 chapters and an Appendix; DR. YOUNG has, in the 111 pages of excellent reading matter, given us a very practical and most useful guide to the springs and baths of Carlsbad. Having himself been a resident of India for many years, he has explained his subject with

a special view to the exigencies and needs of dwellers in the tropics.

The opening chapter is devoted to information regarding how to get to Carlsbad, cost and mode of living, physicians, springs, baths, &c. For those who can afford an outlay of £50 and can obtain 3 months' privilege leave, this chapter will give full particulars as to how the time may be most profitably spent.

The next two or three chapters are devoted to explaining methods of conducting a Carlsbad course of treatment, diet, drinks, amusements; the various kinds of baths are explained, e. g., the Russian, the hot salt-water, the mud or peat bath, the pine, the steel, electric baths, &c.

DR. YOUNG also judiciously gives us a chapter on how to carry out the Carlsbad treatment in India, or the "artificial course."

This will no doubt be a boon to those whose limited income preclude their going to Carlsbad. There are two methods described, the first is to procure 2 dozen bottles of Carlsbad sprudel water, and the second (an alternative) 2 bottles of Carlsbad salt (powdery form). DR. YOUNG also gives in a clear, tabulated form indications where the treatment will be most useful, and enumerates the diseases wherein it will do most good, such as malarial enlargements of liver and spleen, chronic dysentery, diarrhoea, anaemia, dyspepsia, gout, rheumatism, diabetes, &c., mentioning at the same time those diseases where it is contra-indicated. Full directions are given as to how and when to apply the course of treatment.

The remaining chapters deal with the incompatibility of acids with the Carlsbad treatment, chemical constitution of the Carlsbad water and salt, tropical diseases for which Carlsbad is specially suitable, its special action, on some forms of dyspepsia common in the tropics, and hints for tropical residents.

A MANUAL OF MODERN SURGERY, GENERAL AND OPERATIVE. By John Chalmers DaCosta, M.D., Demonstrator of Surgery, Jefferson Medical College, Philadelphia; Chief Assistant Surgeon, Jefferson Medical College Hospital, etc. (Publisher: W. B. Saunders, 925 Walnut Street, Philadelphia.) Price \$ 2.50.

The aim of this manual, viz., to present in clear terms, and in concise form, the fundamental principles, the chief operations, and the accepted methods of modern surgery, with which DR. DACOSTA started out, has been amply and creditably fulfilled in his excellent little work on surgery.

The opening chapter is devoted to a full and succinct account of bacteriology—a most important subject for the better appreciation of disease and application of anti-septics.

Considerable matter is devoted to fractures and dislocations. So important as these cases are of daily occurrence affording excellent material for clinical study. Ophthalmology, gynaecology, otiology, otology and laryngology have not been dealt with, as being best relegated, in this age of advanced specialized science, to specialists.

Some of the remedies recommended, though more popular in America than here, such as peroxide of hydrogen

campho-phenique, camoline, &c., will no doubt be adopted for more general use in time to come. The print throughout is beautifully large and clear, the illustrations good and the tinted plates representing examples of bandaging excellent while the paper is superior. On the whole, Dr. DaCosta may be congratulated upon the production of a work of great practical use alike to the student and the surgeon. Dr. DaCosta's "Manual of Surgery" stands mid-way "between the complete, but cumbersome textbook and the incomplete but concentrated compend."

FALITA RASAYANA. By Chuni Lal Bose, M.B., F.C.S. Lond. Price Re. 1-8.

We have received a copy of Falita Rasayana, a book on practical chemistry in Bengalee, by Assistant Surgeon Chuni Lal Bose, M.B., F.C.S., one of the Chemical Examiners to the Government of Bengal. The subjects treated of in the book are those prescribed by the Calcutta University for the first M.B. and L.M.S. examinations, and we are glad to be able to say that these have been dealt with ably and at some length. After explaining the most important principles and laws which build up the structure of the science of chemistry, the author goes on describing in detail the various processes employed in the detection of *bases* and *acids*. In describing the tests for each metal, the author has given a short sketch of its physical and chemical characters as well as the sources from which it is obtained. Much useful information of medico-legal importance is to be found in the chapters on arsenic, hydrocyanic acid and vegetable alkaloids, which would be of use to medical men concerned in medico-legal work. The chapter on the analysis of urine has been written with a thorough knowledge of the subject, and the tests of some of the principal abnormal ingredients, such as *albumen*, *sugar*, *bile* and *chyle* have been brought up to date. The application of the tests recommended in the book at once suggests a thorough, practical acquaintance of the author with his subject. The busy medical practitioner, who has to do a few analyses of urine every morning, and Assistant Surgeons and Hospital Assistants who have to do a great deal more in the hospital will, we are sure, find in this book valuable help in their work. The diagrams of the apparatus and of the ordinary deposits have been neatly executed and a glossary of Bengalee scientific terms with their English synonyms has been given for easy reference. The book is, we believe, the first of its kind in the Bengalee language, and we think it is a valuable addition to scientific vernacular literature. It is fit to be made a text-book in the vernacular medical schools in Bengal, and we would heartily recommend this book to students and practitioners of medicine.

The Report of the Opium Commission, which has been prepared by the Home Department, has now received the Viceroy's approval, and will be published for general information without delay.

Mr. F. X. deAttaides, third grade Civil Assistant Surgeon of the Imperial list, having passed the prescribed examination for advancement, is promoted to the second grade, from the 2nd June, 1894.

Surgeon-Colonel Harvey is to be appointed Principal Medical Officer with the Punjab Army under the new scheme if he does not get the P. M. O.-ship of the British Forces.

Government Medical Gazette.

GOVERNMENT OF INDIA.

The services of Surgn.-Col. D. O'C. Bays, M.D., I. M. S., (Beng.) Offg. Insp.-Genl. of Civil Hosps., Punjab, are replaced at the disposal of the Milly. Dept. from date on which he relinquished charge of his duties.

The Governor-Genl. in Council is pleased to appoint the following gentleman to be a Fellow of the University of Calcutta:—

Surgn.-Maj. G. S. A. Ranking, M.D., Secy. to the Board of Examiners.

Surgn.-Col. F. B. Scott, M.D., C.M.G., A. M. S., P. M. O. Quetta Dist., leave (p.a.) for eight months.

Dr. H. E. Wells, M.B., is temply. apptd. as an Un-covenanted Med. Offr. and posted to Burma.

On relief by Hosp. Asst. Rahmat Ali, Hosp. Asst. Partab Singh is re-posted to the Stud Depot, Saharanpur.

The services of Asst. Surgn. L. J. Reilly are placed at the disposal of the Chief Commissioner of Burma.

Asst. Surgn. H. A. J. Gidney is granted privilege leave for 15 days, 21st Dec. 1894.

Dr. F. X. deAttaides, 3rd grade Civil Asst. Surgn. of the Imperial List, having passed the prescribed exam., is promoted to the 2nd grade, 2nd June 1894.

BENGAL GOVERNMENT.

Asst. Surgn. Upendra Nath Sen made over Malda Intermediate Jail to Surgn.-Capt. G. Jameson, 1st Jany.

Asst. Surgn. Hari Charan Sen, offg. at the Kishoreganj sub-divn. and Hybturnger Dispy., leave for three months.

Surgn. Lieut.-Col. K. P. Gupta made over Barisal Jail to Surgn.-Capt. J. G. Gordon, 7th Jany.

Asst. Surgn. Narendra Nath Gupta made over Noakhali Jail to Surgn.-Capt. T. Grainger, 5th Jany.

Asst. Surgn. Mahendra Nath Dutt to do superny. duty at the Med. Coll. Hosp., Calcutta, 4th Jany.

Asst. Surgn. Nil Kanto Chatterjee to do superny. duty at the Med. Coll. Hosp., Calcutta, 9th Jany.

Asst. Surgn. Kali Prasanna Banerjee, a superny. at the Med. Coll. Hosp., is apptd. to have temply. charge of the sub-divn. and dispy. at Silliguri, Darjeeling Dist., vice Asst. Surgn. Gopal Chunder Dey, on leave.

Asst. Surgn. Kasai Nath Ghosh, leave for three months.

Asst. Surgn. Umces Chunder Baerjee leave for two months, 22nd Nov. 1894.

PUNJAB GOVERNMENT.

On transfer from Shahpur, Dr. J. A. Fink assumed charge of the civil med. duties of Karnal on 24th Dec., relieving Asst. Surgn. Abnaahi Ram.

Surgn.-Col. J. Cleghorn, M.D., resumed charge of the duties of Insp.-Genl. of Civil Hosps., Punjab, 27th Dec., relieving Surgn.-Col. D'O. C. Bays.

Brig.-Surgn. Lieut.-Col. G. Massey, Civil Surgn., resumed charge of his duties at Murree on 6th Jany., relieving Asst. Surgn. W. Clarke, Lawrence Memorial Asylum.

Hosp. Asst. Chirag-ud-din, from the Teri Dispy., Kohat Dist., to the Rawalpindi Civil Hosp., for genl. duty, 3rd Jany.

Hosp. Asst. Ghazi-ud-din, Dailhouse Dispy., two months' priv. leave, 9th Jany.

Hosp. Asst. Ganesh Das, doing genl. duty at the Mayo Hosp., Lahore, to the Civil Hosp., Delhi, for genl. duty, 26th Dec.

Hosp. Asst. Amir Bakhsh resumed charge of the City (Old) Dispy., Amritsar, 5th Jany., relieving Hosp. Asst. Sawan Mal, transferred to the City (New) Dispy., Amritsar, 6th Jany., relieving Hosp. Asst. Jhande Khan, granted three months' priv. leave.

Hosp. Asst. Amir Khan, doing genl. duty at Karnal, was apptd. to the Karnal City Branch Dispy., 31st Dec., relieving Hosp. Asst. Nanak Chand, apptd. to the charge of the Karnal Jail and Police Hosps. 1st Jany., relieving Hosp. Asst. Chandan Lal, retired.

Hosp. Asst. Shadi Khan, Shabkot Dispy., Gujranwala Dist., three months' priv. leave, and was relieved on 30th Dec. by Hosp. Asst. Fazl Ihsai, transferred from the Jhang Dist.

Hosp. Asst. Amir Shah to do genl. duty at the Mayo Hosp., Lahore, 8th Jany.

The priv. leave granted to Asst. Surgn. Rias Bhagwan Das, Kaika Dispy., is extended by fourteen days.

BOMBAY GOVERNMENT.

Surgn. Lieut.-Col. F. A. Rowland, I. M. S., is permitted to retire from the service. 22nd Feb.

Surgn. Lieut. E. M. Moore has been apptd. to the med. charge of the Baroda Resdy. in addition to his duties as Med. Offr., 1st Regt. Bombay Infy., 26th Dec.

Asst. Surgn. Bhaa Govind, L.M. & S., is promoted from the 3rd to 2nd class, 17th Dec.

Surgn.-Capt. J. L. T. Jones, M.B., and H. Herbert, F.R.C.S., respectively delivered over and received charge of the Kaira Prison on 20th Dec.

Surgn.-Capt. H. Herbert, F.R.C.S., and Asst. Surgn. Dorabhai E. Kothawala respectively delivered over and received charge of the Kaira Prison on 20th Dec.

Surgn.-Maj. R. W. S. Lyons, M.D., and Asst. Surgn. P. P. Moolan respectively delivered over and received charge of the Ratnagiri Prison on 20th Dec.

The services of Surgn.-Maj. C. G. W. Lowdell, I. M. S., are placed at the disposal of Govt. for permanent civil employment.

Asst. Surgn. Phirozshah Palanji Mullan, L.M. & S., on genl. duty from 25th Dec.

Asst. Surgn. Palanji Hormasji Dadachanji, L.M. & S., priv. leave for one month.

Surgn.-Maj. C. G. W. Lowdell, to be Civil Surgn., Nasik, *vice* Surgn. Lieut.-Col. P. Murphy, M.D., retired.

Surgn.-Capt. H. Herbert and Surgn.-Lieut. W. Carr Sprague respectively delivered over and received charge of the Rajkot Prison on 18th Dec.

Surgn.-Lieut. W. Carr Sprague and Surgn. Lieut.-Col. F. C. Barker respectively delivered over and received charge of the Rajkot Prison on 21st Dec.

Asst. Surgn. P. P. Moolan and Surgn.-Maj. J. Crimmin respectively delivered over and received charge of the Ratnagiri Prison on 25th Dec.

CENTRAL PROVINCES GOVERNMENT.

Civil Hosp. Asst. Pandurang Laxman, doing duty under orders of the Civil Surgn., Seoni, is temply. apptd. to the charge of the Jail and Police Hosp., Seoni, *vice* Civil Hosp. Asst. Ganesh Sitaram, temply. apptd. to the Laknadon Branch Dispy., *vice* Civil Hosp. Asst. Lal Mahomed, apptd. to do duty at the Chappara Cattle Fair, Seoni Dist.

N.-W. P. AND OUDH GOVERNMENT.

Asst. Surgn. Bonomali Pal, in charge of the sadar dispy., Kheri, priv. leave for three months, 15th Jany.

Consequent on the retirement of Brig.-Surgn. Lieut.-Col. W. R. Hooper, Civil Surgn., Lucknow, Surgn. Lieut.-Col. B. O'Brien, Offg. Civil Surgn., 1st class, to be confirmed in that class, and to be posted to the Allahabad Dist. on his return from leave.

Surgn.-Capt. J. M. Crawford, Offg. Civil Surgn., held charge of the Civil Surgeoncy of Allahabad from the 7th to the 10th Jany.

Surgn. Lieut.-Col. A. J. Willcocks, Civil Surgn., on return from deputation, to the Agra Dist.

Asst. Surgn. Annoda Prasad Datta, on being relieved of the charge of the Sadar Dispy. at Bareilly, to the charge of the Sadar Dispy. at Kheri.

Surgn. Lieut.-Col. J. McConaghey, Civil Surgn., from Allahabad to Lucknow.

Surgn.-Maj. C. P. Lukis, Civil Surgn., from Agra to Shahjahanpur.

Surgn.-Capt. J. Morwood, Civil Surgn., from Shahjahanpur to Basti.

Surgn.-Maj. F. C. Chatterjee from Basti to Pilkhiti.

Asst. Surgn. Dalip Singh, on reserve duty at Lucknow, to the charge of the Karwi Dispy., Banda.

Hosp. Asst. Muhammad Boshan, on reserve duty at Lucknow, to hold charge of the Chunar Dispy., Mirzapur Dist., *vice* Asst. Surgn. Binode Behari Ghose, granted leave.

Asst. Surgn. Nandendra Chandra Mukerji, in charge of the Sadar Dispy., Fatehpur, held charge of the civil med. duties of the Fatehpur Dist., in addition to his own duties, from the 2nd to the 18th Jany.

Asst. Surgn. Shasthiwar Rao, Rai Bahadur, on return from leave, to the charge of the Sadar Dispy., Bareilly.

Asst. Surgn. Prasad Har Churamani, on being relieved of the charge of the Civil Dispy., Allahabad, to the charge of the Sadar Dist. at Rae Bareilly.

BURMA GOVERNMENT.

Asst. Surgn. L. J. Bally left Milly. Prison, Lucknow, 18th Dec.

Asst. Surgn. F. X. deAttades, three months' priv. leave, 8th Nov.

Hosp. Asst. Salik Ram left Civil Dispy., Fort Stedman, Southern Shan States, and assumed charge of the Civil Dispy. Taunggyi, 20th Nov.

Hosp. Asst. G. Francis left Genl. Hosp., Bangoon, and assumed charge of the Civil Dispy., Katha, 5th Dec.

Hosp. Asst. G. Francis left Civil Dispy., Katha, and assumed charge of the Civil Dispy., Wuntho, Katha Dist., 14th Dec.

Hosp. Asst. G. Francis assumed, as an additional duty, charge of the Police Hosp., Wuntho, 14th Dec., *vice* Hosp. Asst. Tijumal Hussain.

Hosp. Asst. Hem Chandra Koyal left Police Hosp., Monywa, Lower Chindwin Dist., and assumed med. charge of the Chin Hills Battalion Military Police, proceeding to Tiddim, 17th Dec.

Hosp. Asst. Tijumal Hussain left Civil Hosp., Wuntho, Katha Dist., and assumed charge of the Police Hosp., Katha, 21st Dec.

Hosp. Asst. Parakhit Chandra Rai left Police Hosp., Bhamo, and assumed charge of the No. 2 Matin Escort at Bhamo, 22nd Dec.

Hosp. Asst. J. N. Roy Chowdry left charge of the Ry. Dispy., Yamethin, and assumed charge of the Ma Valley State Ry. Hosp., Mohayin, 26th Dec.

ASSAM GOVERNMENT.

Surgn.-Capt. E. C. Hare, I. M. S., will be employed, until further orders, as a Superny. Medical Officer in Assam from the date on which he was relieved of his duties as Offg. Civil Surgn. of Kamrup.

Surgn.-Capt. F. H. Burton-Brown, M.B., Med. Offr., 43rd Gurkha Rifles, is, with the consent of the Military authorities to hold civil med. charge of the Naga Hills Dist. in addition to his military duties, 25th Dec.

Asst. Surgn. Pramatha Nath Banarji held temply. civil med. charge of the Naga Hills Dist. in addition to his own duties, from the 8th to the 24th Oct.

Hosp. Asst. Abdul Jalal, a superny. in the Kamrup Dist. is transferred to the Nowgong Dist., and is apptd. superny. under orders of the Civil Med. Offr., 31st Dec.

Sick leave for one month, from the 27th Dec., is granted to Hosp. Asst. Jadab Gobinda Biswas in extension.

Hosp. Asst. Karam Ali Hazarika, whose services were transferred to the Assam-Bengal Ry. Company, was, on transfer into the Govt. service, employed as a superny. at Nowgong under orders of the Civil Med. Offr. from the 9th Oct. 1894 to the 4th Jan. 1895.

DOMESTIC OCCURRENCES.

The charge for inserting a Domestic Occurrence is Rs. 1. for subscribers and Rs. 2. for non-subscribers, which should be forwarded in stamps with the announcement.

BIRTHS.

DEANE.—On 8rd Jany., at Moradabad, the wife of Surgn.-Maj. W. Deane, Civil Surgn., of a daughter.

DENNIS.—On the 22nd Jany. 1895, at Delhi, the wife of Surgn.-Maj. George Dennis, of a son.

HUDSON.—On 22nd Dec., at Tanjore, the wife of the Rev. H. Hudson, M.R.C.S., of a son.

BORAH.—On 17th Jany. at Sibsagar, the wife of Surgn.-Maj. S. Borah, I. M. S., of a daughter.

MARRIAGES.

FRANCIS—D'CRUZ.—On 2nd Jan., at St. Matthias', Vepery, Madras, by the Rev. A. H. Brittain, Chaplain, Charles Frederick Francis, Civil Apoth., North Arcot, to Pauline, eldest daughter of B. M. D'Cruz, Esq., Depy. Collector.

PIRES—Fernandes.—On 19th Jan., at Sholapur, by the Rev. Fr. A. DeMonte, assisted by the Rev. Fr. M. F. De Sousa, Surgeon J. O. Pires, to Marianne, the third daughter of J. L. Fernandes, Esq., of Mangalore.

DEATHS.

CORNELIUS.—On the 14th Inst., at the Station Hospital, Peshawar, Charles Edward Cornelius, Asst. Surgeon, I. M. S., the dearly beloved son of the late Geo. Edward Cornelius, and Mrs. Sara Eleanor D'Luz Vieira, aged 24 years, 4 months and 29 days, R. I. P.

DUCKWORTH.—On 3rd Jan., at Madras, Isabella Duckworth, relict of the late Apothecary John Duckworth, aged 64 years.

NOTICES TO CORRESPONDENTS.

A. L. M. (Jalpaiguri).—We referred your case to the Principal of the Medical College. Dr. Bomford says you must pass the F. A. Examination, attend the Calcutta Medical College for three years, and then appear for your examinations. This concession is allowed to you as you are a licentiate of an Indian medical school. This is the rule: if you wish to have an exception made to this rule, apply to the Registrar of the University of Calcutta.

A. R. C. (Gwalior).—Many thanks. Later on.

P. R. C. (Karnal).—We have already noticed the favorable opinion of the residents of Karnal on Civil Surgeon Marchant's work.

K. R. D. (Chakrata).—Too late for this number.

M. S. C. (Trichinopoly).—Later on.

V. J. R. M. (Manamalkudi).—Your letter will receive early consideration.

H. P. B. (Pachbadra).—As we did not mean to publish your letter, we did not keep it.

W. J. S. (Madhapur).—We will try and find space for your letter later on.

ACKNOWLEDGMENTS.

We acknowledge receipt of the following with thanks:

THE SERUM TREATMENT OF PHTHISIS.

THE treatment of phthisis by the serum of asses is discussed at length by Dr. Arthur Gamgee (*The Lancet*), who has personally investigated Dr. Viquerat's claims. The theory upon which the treatment is based is that the ass and the mule are almost absolutely immune to tuberculosis. Hence their serum will confer an artificial immunity against diphtheria. Viquerat admits that asses may be inoculated with tuberculosis, but they have the disease mildly and always recover. He increases their immunity by inoculations of tubercle bacilli. On the forty-fifth day, when spontaneous cure has already been more than completed, the animal is used to supply the curative serum. With this object it is bled, and the blood is allowed to stand over ice, so as to allow it to clot and to permit of the separation of serum. To this serum from 0.5 to 0.75 per cent. of carbolic acid is added, and it is then stored in stoppered bottles until required for use. About twelve cubic centimetres are injected every third day. Viquerat states that when the immunized serum of the ass or mule is injected every second day into guinea-pigs, which have been fifteen days previously rendered tuberculous by the inoculation of active tubercle cultures, the tuberculous glands which had become enlarged and perceptible rapidly become smaller and disappear, while the animal, instead of dying fourteen or fifteen weeks after the inoculation, regains perfect health. Twenty-five cases of human tuberculosis are reported, but the results of the treatment are not yet very brilliant.

Original Articles.

Sanitation in India.*

By SURGEON LIEUTENANT-COLONEL W. G. KING,
M.B., D.P.H., I. M. S.

*Being the Presidential address to the Public Health
Section of the Indian Medical Congress.*

ON first being informed that the Health Section of this Congress had done me the honor of electing me President, I necessarily felt a doubt as to whether I ought to accept so responsible a position for which I cannot help feeling I am ill-fitted. I, however, understand that our Bengal brethren, with whom the happy idea of holding this Congress originated, have, as far as possible, reserved for their visitors all posts of importance. It is thus I find myself possessed of the pleasure of being first President—let us sanitarians say whilst at a safe distance from enthusiasts in other branches of our glorious profession—of the most important section of the first Indian Medical Congress. Allow me, gentlemen, to thank you sincerely for the honor afforded me, and, if I may be permitted to so regard it, the Presidency in which I have the privilege to serve.

Although this is the first Medical Congress in this country, it is doubtless not the first time that wise heads have been shaken in the discussion of matters sanitary. The laws of MANU could not have seen the light, unless there had existed in ancient India, a section of the educated classes who regarded sanitation as of so great moment that, to bring it home to the masses, it was desirable to weld its laws with their religion. None but men possessed of strong sanitary instincts would have considered it necessary to render it illegal that filth should be brought near them, or would have taken care that those following noxious trades, and the "great unwashed" generally should not approach them. It is true these sanitary laws are known as "rules of caste," but neither their origin nor intention can be mistaken. Were the most recent refinement of scientific research—the bacteriologist—to have it all his own way, I verily believe we should find ourselves bound down by rules as rigid as those of caste; none but men who on penalty of excommunication from the guild were in the habit of completely washing their bodies and clothing a certain number of times daily, who would undergo special purification and a stage of segregation if by force of circumstances brought in contact with unkindly microbes, would be permitted to handle our drinking vessels or prepare food for us. We should find it necessary to purify ourselves carefully after our clins had been handled by the barber, or we had attended a funeral; we should all be bound to prevent saliva, excrement, blood and other distilling matter reaching our public water-sources; we should regard sunlight and the "living earth" as the great purifiers. Laws such as these must in their day have been of vast benefit to the members of the guilds which were called upon to live in the midst of an alien and, apparently, not over-cleanly race.

The Hindus, however, by no means possessed a monopoly of a belief in sanitary laws. Mahomedans brought with them the dicta that "cleanliness is the key to heaven," and that "the preservation of the life of man is but second to the command of God." In this matter, they did not halt at mere theory, as witness the magnificent infiltration galleries, and distribution of enormous volumes of pure water in pipes under pressure in Aurangabad, Ahmednagar, Burhanpur, and other localities. In proof of the fact that these works, designed by the Sanitary Engineer of the period before cast-iron pipes had been dreamt of, have fulfilled their function, I may mention that the city of Aurangabad—although the protection of its water-supply is by no means perfect according to modern notions—has, during the 300 years of their existence, been remarkably free from cholera. Indeed, it frequently occurred that, whilst the neighbouring British cantonment suffered severely, the city of Aurangabad, within a mile of it, remained fairly free. The reason for this comparative immunity being self-evident, in that in the one case a much-defiled stream is the water-source, in the other a partially-protected supply from a good origin, the enlightened Government of H. H. the Nizam lately sanctioned the opening of water-works for the cantonment. It is a curious commentary upon the principles pursued in these ancient sanitary engineering works, that MR. MARRETT—the able Engineer for the modern works—has also drawn his supply from infiltration galleries, the data as to the yield of which he was aided in calculating by an examination of those formed three centuries ago by MALIK UMBER and AURANGZEB.

But it has been with Hindus and Mahomedans alike, as it has been with the Jews—the other instance where hygienic laws had been knitted to religion—the letter of the law has been fulfilled, but the spirit has been forgotten; thus, alas, the India of to-day is a by-word amongst the nations as to neglect of sanitation, and is regarded as the home of that much-dreaded pest—cholera. Hence it is in this country, there exists an enormous field for the labors of that modern branch of the medical profession which we recognize as sanitation. Well may the qualifying term of modern be applied to this science of the West, when compared with the rules of caste of the East with which there is so much akin. The great cholera scare in Great Britain of 1849 pointed to the necessity of concerted public action where grave epidemics were feared; the waste of human life and the hardships to which our troops were subjected in the Crimea, taught the public the necessity of attending to the warning voice of hygiene. As you all know, the outcome of this movement was a demand that our soldiers, when called upon to risk their lives for their country in fair fight, should not be condemned to die by disease born of filth and engendered by ignorance. This was responded to by the appointment of a Royal Commission, and the founding of the Army Medical School at Chatham and, subsequently, Netley. When quiet times succeeded the troublous days of the Indian Mutiny, officers trained in these schools at the feet of that noble and learned man, the late Professor PARKES, could not fail to be imbued with his unselfish spirit, and thus whilst on the one hand they toiled in the various civil stations to which they were attached to start medical

* Sent to the printer for publication.

institutions, on the other, they did not forget their duty as sanitarians. They formed Sanitary Committees whose constant representations to the authorities as to the conditions of the civil populations, resulted in the birth of Municipalities and Local Fund Boards, charged with the sanitary administration of urban and rural areas, respectively. Under their care also, rose great medical schools, which have afforded training to the important class of private medical practitioners which now shares with the Indian Medical Service the responsibilities of medical and sanitary work in this country, whom we have the pleasure in this Congress of welcoming as valued colleagues, capable of aiding us with their experience and advice in the common object of sanitary reform. These advances were made slowly, but, during the last 15 years, the progress of hygiene has been in geometrical proportion. Investigations in the various sciences which go to make hygiene are now pressed forward with feverish haste, and we no longer wait till the experimenter has settled with his publishers for a book to see the light, perhaps a year after the completion of his work; we demand that intelligence shall be sent us by wire, and brook no delay in being told that KOCH has discovered the bacillus of tubercle; KLEIN the streptococcus of scarlatina; PASTEUR an inoculation against rabies, and HAFKINE against cholera; that HANKIN has demonstrated a new toxic-albumin, and SIMPSON the true origin of vaccine lymph; that MANSON has taught us to dread the mosquito, and CUNNINGHAM to think less unkindly of the comma bacillus; that the Incid pen of HART has stirred the length and breadth of the civilized world in demanding better sanitary care of the "home of cholera;" and that Miss FLORENCE NIGHTINGALE preserves intact her sympathy with sanitary advances in this country.

The Royal Commission of 1863, to which India is so greatly indebted for its awakening into sanitary activity, declared that the mortality of the European soldier was equivalent to 69 per 1,000 amongst the men, and 31 per 1,000 amongst the officers; while in 1860-61 in jails for native prisoners the mortality was 67.0 *per mille*. I need not trouble you with a statement of what the mortality was amongst the civil native population, as our registration statistics were at that time, and are up to date, far too defective to enable trustworthy figures to be furnished. In accordance with the advice tendered by the Royal Commission, advising bodies were, in 1864, attached to each Government in the form of Sanitary Commissions. In 1866 these were replaced by single officers—Sanitary Commissioners. Under their advice, radical improvements were made in the dietaries, in the buildings, and precautionary methods pursued in barracks and jails. The death-rate of the European soldier is now about 12 *per mille* from all causes, and that of our native prisoners about 29 *per mille*. These results are undoubtedly highly satisfactory, and can be ascribed to no other cause than the placing of the populations concerned under improved hygienic conditions.

In regard to jails, although here and there minor insanitary conditions still exist, it may fairly be said that, as to diet, labor, and dwelling accommodation, the native prisoner is well off. I do not believe the same can be said so fully either of the British soldier or native sepoy. The period of progress inaugurated in 1864 has not been consciously maintained. Typhoid fever claims far too many

victims for it to be imagined that the surroundings of the British soldier are free from reproach; for he forgets that THOMAS AKEINS has his own little ideas of what is good for his internal economy, and imbibes without thought of its origin, vile "cool drinks" prepared for him in the bazaars; but we cannot well regard this—albeit preventible cause—as sufficiently explaining our losses. In the matter of food-supply, which demands the special knowledge, not of the medical man only, but also of the chemist and analyst, our Army authorities have become impatient of control or suggestion by the medical profession, and we find the modern tendency is to attempt to educate military officers to do the work of the sanitarian; so that, except at the expenditure of much representation and the risk of considerable opprobrium, it is impossible for the medical officer to reject, that which the combatant officer officially responsible for food inspection, has already passed. It is highly desirable that military officers should possess the training indicated, just as it is also desirable that medical officers should have sufficient military training to defend the wounded or themselves in desperate positions, as they have so often managed to do without possessing that advantage. But, whilst I would demand that in action the lives of soldiers should be entrusted to professional combatants, it seems but meet that all matters affecting health should be under as complete control by the sanitarian as the exigencies of military service would permit. Recent reports by officers of the Army Medical Staff have shewn that the dry-earth method of night-soil disposal in certain cantonments is far from being above suspicion. Nor, in the more grave matter of water-supply, have our cantonments, in the generation that has elapsed since the appointment of the Royal Commission, been placed in a completely satisfactory condition. In two at least of our important military stations in the Madras Presidency, the water-supply is such as to leave little room for doubt that, however much the soldier is himself to blame in contracting typhoid by his gustatory peculiarities in the midst of the bad hygienic conditions of native bazaars, there is ample room for his contracting the disease nearer his barracks.

In Bangalore, the troops are provided with water from a tank which is supplied by an open channel that passes through a native bazaar, but is duly kept clean by means of sweepers, whose services, be it noted, are considered necessary. Forming part of the wall of the supply channel is the main sewer from the same area. This sewer is ingeniously arranged, so that when over-charged with storm water—brought thither by open drains which are destined normally to receive the sewage from native houses—relief is obtained by discharge into the water-supply channel, and thus into the tank. We are consoled by the statement of the Engineer authorities in charge, that overflow only occurs about five times per annum. Again, in Madras the so-called "Seven Wells" water is supplied to the British troops. This water has been pronounced "bad" by the Madras Chemical Examiner, whilst a sanitary survey shews that enormous collections of rubbish containing focal matter deposited by the Municipality sewage farms, and graveyards, are within the same sub-soil sheet as the sources. Both in Bangalore and in Madras the British troops have suffered from typhoid fever. They are said to be valued at £100 per man.

But there is one class of disease to which the British soldier is subject, which in the plenitude of the wisdom of Exeter Hall it has been determined that prevention shall not be exercised. In India during 1892, there were inefficient for certain periods during the year 27,000 men, or 410 per mille of the average strength, by reason of admission to hospital for venereal disease; and 206 were invalided from this cause during the year. Yet, by the repeal of certain clauses of the C. D. Act, the hand of Government has been stayed at the instance of a narrow-minded section of the British public. In the name of morality, in the name of Christianity, the erring bachelor has been dealt with on the "serve-you-right" policy, possible only of adoption by minds devoid of the power of recognising in what true humanity exists. To what punishment would not these purists condemn the man who having warned his child that if he played with fire he would burn himself, complacently saw it commit the act of disobedience and literally be done to death; yet, the policy of non-interference entails present suffering in our fellowmen and their companions in immorality from a disease that may be transmitted to a wife and the innocent infants of a future union. I know of no law of God or man that can give countenance to a policy so cruel. The only possible excuse that can be offered for the leaders of this movement is that they hoped that fear of acquiring disease would act as a deterrent. In this they have exhibited gross ignorance of the laws of Nature; not the biggest scare-crows ever made—and the soldier is aware that the dangers are real enough—would quench human passion. Neither can it be pleaded that the measure protects women from falling. On the opposite, a system of supervision prevents many from subjecting themselves to degradation so manifest, and must often have saved those from final ruin whose wings have been singed. In my opinion, the result of the repeal of the law has been to extend the circle of immorality, and to bring within the area women who might otherwise have escaped. Nothing short of the moral training that would demand that mankind be "temperate in all things" can afford the result arrived at, and it is to this end, combined with endeavours to make gymnastics and all manly exercises receive far more encouragement than at present at the hands of the authorities, that all efforts should tend.

The sanitary conditions under which the native troops serve are certainly much superior to those of the average civil native population, and undoubtedly, the small mortality, and especially their comparative freedom from small-pox and cholera, exhibit the results of the supervision exercised. But in respect to native followers, there can, I think, be little doubt, that defects exist. An army wasteful of its transport animals must suffer seriously in the long run, to say nothing of the enormously increased cost to the country employing them. The last Afghan war seems to have taught the necessity for care in this particular, and officers and men now receive training as to loading and unloading that was before little thought of. But I have failed to see any precautionary measures suggested, or adopted, as a result of the loss of life amongst native followers which occurred in the various expeditions of late years in Burma. I cannot here take up your time

with details, but I would ask those who have interest in these questions, to balance the diet, fuel allowances, and shelter provided for followers, against the work expected of them as weight-carriers on lengthy marches, and compare these data with those applicable to native combatants employed side by side with them, and ascertain for themselves whether there does not exist some physiological error which in part accounts for the invaliding and death-rate of that useful class of men. In my humble opinion, these matters should have been carefully sifted, and the medical and sanitary experience gained from our little campaigns in Burma should have been made available for possible heavier struggles in the future.

In the case of troops and jails, it is but demanded that the sanitarian should convince the ruling authorities as to the necessity for action, for the latter to find funds and issue orders. With the civil population, the problem is, however, much more complex. It embraces questions as to the sanitary discipline of 212 millions of people inhabiting the most diverse climates, speaking different languages, possessed of different customs, and, above all, bound hand and foot by prejudices which they are but too apt to confuse with religious instincts. Undoubtedly, the foundation of all sanitary efforts must be the existence of suitable laws to support the sanitary executive. Since 1863 we have seen laws passed under which municipalities and local fund bodies have sprung into existence; these, in their infancy, were largely controlled by Government officials, but of late years, under the Local Self-Government movement, have been placed in the hands of representative native gentlemen. In the case of the Madras Presidency, the Act dealing with the rural tracts has already, since its inception in 1871, undergone one revision, and is now being remodelled by Government. The same is to be said of the District Municipalities Act. For the large town of Madras, revision of the special Act applicable, has also been accomplished. These alterations were largely prompted by the necessity for increased sanitary procedure. In regard to fairs and festivals, increasingly stringent regulations have had some influence in diminishing the appalling loss of life, which the insanitary conditions under which most of them used to take place brought about; but, on this point, much remains to be done. Careful records of factors affecting the health of populations, as to the progress of epidemics, and sanitary subjects generally, may be reckoned by the lakh. Attempts to ameliorate existing conditions by petty expenditure, and the giving of advice have also everywhere been made in our rural tracts and minor towns. The Vaccination Department has not been idle, and has made its influence felt upon mortality distinctly; but no one has yet been able to convince the Government of India that the employment of a poorly-educated and ill-paid vaccination staff throughout the country, is incompatible with the attainment of full results. In rejecting a scheme for employing medical subordinates in the Madras Vaccination Department in 1868 the Government of India informed that of Madras, that "the duties" of vaccinators "are purely mechanical," and the rates of pay proposed "are needlessly high, from a desire to attract men of education and respectability such as are not required, inasmuch as

they would be a more expensive agency than is requisite for the purely mechanical duties of vaccinators." During the last 64 years in the Madras Presidency, 201,304 deaths were registered from the preventible disease of small-pox. Taking into account the probable number of survivals from these attacks at 64·3 per cent., it is calculated that—without taking into account the capitalised value of lives—there must have resulted during sickness and upon funeral ceremonies an unproductive expenditure of 51 lakhs of rupees, if it be presumed that the persons attacked occupied no higher position than the cooly gaining Rs. 5 per month.

But in the practical application of sanitation, outside the limits of the capitals of the various Governments, our advance has been but little. Unfortunately for the country, it was possible for those responsible for this absence of progress to shelter themselves behind a motto that was so frequently applied to the Sanitary Department that it became a part of the sanitary creed of the day. There were, it was repeatedly stated, prejudices to overcome; therefore *festina lente* must be the guiding principle. The phrase saved much labor, and it became the business of no one to enquire whether these prejudices really were of so serious a nature as to clash with the people's more deeply-seated and legitimate opinions of religion, and—it saved money. Year after year, it was pointed out that if the principles evolved from the investigations of the sanitarian were to be given effect to, specially trained Engineers to execute sanitary schemes, in consultation with Sanitary Commissioners, were requisite. At last the Secretary of State acted upon these recommendations, and the majority of local Governments are now provided with Sanitary Boards having a Sanitary Engineer as a member. Further, the important principle that Government must aid sanitary advance by direct allotment of funds has now been conceded, and local Governments are responding to the call; in the Madras Presidency the Government has, since 1890, in the manner of free grants to Municipalities, given the sum of Rs. 13,05,850, besides advancing loans upon very favorable interest to Municipalities for drainage and water-works: 1888—the date of the Secretary of State's despatch on these subjects—may well be reckoned a new era in the sanitation of India. Since this period we have seen the North-West Provinces busy in the revision of its sanitary laws, especially with reference to the accommodation of pilgrims; a Village Sanitation Bill has been essayed in Bombay; and Bengal, under that ardent sanitarian, Sir CHARLES ELLIOT, has excogitated large drainage schemes that, aided by legal measures, are directed against the greatest cause of mortality in this country—malaria: these are measures of the most practical nature which must be far-reaching in their life-saving results. We have seen a well-known bacteriologist appointed at Agra, and to the Sanitary Commissioner with the Government of India a special assistant for bacteriological enquiry, has been attached. Methods of intercommunication between presidencies and between neighbouring districts as to movements of epidemics have been successfully organized. In numbers of the larger towns drainage and water-supply works are in actual progress. But it would be folly to consider there have been

made efforts commensurate with the great work of life-saving before us.

Although, as I have shewn, it has been possible within the last few years to throw off something of the glamour of that thread-worn proverb, there is still enough of the old spirit of *festina lente* prevailing to clog the wheels of progress, and to limit the fuel, the consumption of which makes this machinery exhibit its full value; I refer to that useful article—money. Schemes for sanitary improvements are still built toilfully, yet in hope, are launched upon seas of unbelief, and are wrecked upon the shores of finance. In short, sanitary advance is constantly frustrated by the cry "no funds." In this great assembly of sanitarians representing opinions from all parts of India and of Europe, we may well be permitted to ask without being taxed with captiousness, or, in the case of those occupying official positions, insubordination, whether it really be that no funds are available, or that Government has not yet arrived at a sufficient grade of faith in sanitation to devote to it its fair share of funds. I maintain that sanitation neither receives its fair share of funds, nor that place in the Government of the country that it merits.

I have had no time to enter into statistics on this subject in other presidencies, but taking the case of Madras, I find that from Provincial Funds the average amount spent directly upon sanitation during the last five years was Rs. 44,660 or 0·15 per cent. of the total funds. This expenditure is for a Sanitary Commissioner, aided by a single deputy, who also, under the former officer, is in charge of the Vaccination Department, *plus* an office staff. This represents the total staff devoted solely to sanitary purposes and paid from Provincial Funds, for the care of about 36,000,000 people and an area of country about 141,189 square miles. But for education during the same period, it was found necessary to allow an average of Rs. 12,21,230 per annum or 4·1 per cent. of the total funds. It is further noteworthy that, whilst expenditure on the sanitary staff remained practically at the same figure, for education it has year by year steadily increased, so that although, in 1883-84, Rs. 9,52,778 was thought sufficient, in 1892-93, Rs. 14,06,352 was demanded. This sum includes grants to local bodies and the pay of a Director of Education, who gets a salary of Rs. 2,000—2,250 per month, has a suitable office staff, *plus* an admirable staff of assistants in the form of Inspectors, Assistant Inspectors and Sub-Assistant Inspectors, male and female.

In this statement of expenditure from Provincial funds, no account is taken of grants for buildings for educational purposes, which in the Presidency town alone cost Rs. 13,94,356. The Government has remained so convinced as to the necessity for this outlay, that it has felt it desirable, in the interests of economy, to issue its orders from an ancient building, which is a cross between a barrack and the office of a commercial firm—affording a decided contrast to the magnificent educational buildings such as the Presidency College, the Senate Hall, and Law College which are in its proximity. Even were the provincial grants to Municipalities I have mentioned taken into account, the percentage from Provincial funds for sanitary works and sanitary staff would amount to 0·37 against 4·1 for education, excluding grants for works and buildings.

For 1898 the Educational Department ceases its demand for money only from Provincial Funds. It duly asks and receives its share from Municipal and Local Funds. I find that in 1898, the Educational Department spent from Provincial and Local Funds Rs. 21,32,281 against Rs. 7,88,000 devoted to sanitation, or a proportion of 8.4 per cent. against 2.0 per cent. of the total funds. On combining the figures for Provincial Funds, Local Funds and Municipalities, it is found that education consumes 5.5 per cent. against 3.0 per cent. for sanitation. As far as it has been possible to effect this from the data available, this sum represents net expenditure. The amount spent in sanitation represents the maintenance charges for conservancy staffs and the upkeep of plant for a population of 36,000,000.

There are doubtless other departments which also receive more than their fair share of available funds, and thus tend to render sanitary advance impossible; but I have utilised this instance, as the Educational Department of Madras has long been subject to the well-merited criticism of over-production, whilst like OLIVER TWIST it for ever demands more. In the Madras Presidency, notwithstanding the popular opinion outside our limits that we are "benighted," the land is flooded with B. A.'s and Vakeels; or, in other words, with educated men. The best evidence of over production is the market value of any article, and I may state that the finding of employment of any sort for University graduates is so difficult that they willingly accept posts on pay little better than that of a good class of domestic servants, whilst with Vakeels the earning of a living in strict accordance with legal ethics is becoming increasingly difficult, notwithstanding the extraordinary fondness of the people for litigation. But it may be said that education is the best ally that hygiene could have, and but paves the way for sanitary advance. Well, I have carefully watched results, and have attempted to believe that this is so; but I am driven to the conclusion that this theory must be accepted with reserve. Whilst, doubtless, education has given to us in every part of the country consistent and earnest advocates of sanitation, in a large number of cases practice and theory do not go hand in hand. The average educated man will not scruple in the morning to proceed to the river-side or tank, and perform there his complete toilet, using water that he sees is undergoing contamination within a stone's throw by his male and female brethren; although, in the evening, he will fully grasp the refined hygienic details of the evil results of early marriage, and will give his vote at crowded meetings as to the abolition of the nautch girl. Not only has the Educational Department been guilty of over-production in the higher branches, but they have committed the fatal error of neglecting sufficiently to advance female education. It has apparently been forgotten how powerful and obstinate an advocate the female part of the population is of various superstitious customs. This neglect has rendered it almost impossible for educated natives to carry into their every-day life the practice of sanitation, of which they have duly learnt the theory. In the mental culture of women I, therefore, think has a far more legitimate field for spending of public money than in the over-production of Vakeels and B. A.'s. But, irrespective of this great impediment, it is manifest that

large as the number of educated men is, their influence upon the masses can be but small; where this can best be felt is almost solely in the large towns—the rural population representing the bulk of the people being practically beyond their sphere of influence. This mistake is beginning to dawn upon the public, and the Madras Government is now doing its best to favor primary and technical education—just where their predecessors' efforts should have commenced. This form of education, which will raise the status of the lower classes and assist in developing the long-neglected natural resources of the country, doubtless will effectually aid sanitary advance, and, were it to be understood that the new scheme is to be pushed forward by retrenching the useless expenditure upon over-production in the higher classes of education, the movement would have the full sympathy of those interested in sanitation. But there is every reason to believe that the charges incurred will form increased increments against funds that might otherwise be available for sanitation. If to "hasten slowly" has been the principle enunciated for the guidance of the Sanitary Department, "the people die not slowly; therefore be philanthropic and hasten their education" has been that unconsciously acted upon as regards the Educational Department.

In speaking thus, it must not be imagined that I would prefer not to see the country overrun with highly-educated men. Provided these gentlemen could get a living satisfactorily to themselves, their existence is a distinct factor in the advance of the country; whilst socially their mental culture makes acceptable comrades and friends of men, who would otherwise be incapable of exchanging an idea with their fellow-beings of the West; but I certainly think the time has come to consider, in view of over-production and the more pressing claims of the population upon Government for the preservation of health and decency, whether the higher class of education should not be secured by those desiring this luxury otherwise than at the hands of an elaborate department receiving pay and pensions from Government. I need not say we do not grudge our fellow-officials of the Educational Department the success which has attended their efforts, to persuade Government to give them so large a proportion of the sinews of war. The Sanitary Department has just as great opportunities to plead the cause of sanitation as they have possessed as to education, they have succeeded where we have failed. It is obviously to remedy this state of affairs that we must exert ourselves. If we believe in the enormous importance of hygiene in the saving of human life and suffering, we as a body and as individuals will not rest until we see this country provided with a better share of funds and correctly-organized Public Health Department, capable of investigating and dealing with the causes of disease, and supervising and controlling the methods of expenditure upon sanitation. In undertaking to secure these ends, we may well consider it our duty to press forward at the risk of being regarded by the public as mere "faddists," and men possessed of not the slightest comprehension of what the demands upon State are. This, however, we can well afford to brook. We aim at securing no public praise, but at the attaining of the ample reward—even to a greater measure for which our brethren engaged in medicine and surgery are willing to toil by night and by day; the pleasure of

being the instrument, in God's hands, of relieving suffering and saving life. For the sanitarian is reserved the joy not of seeing the solitary weakly patient day by day gather strength to resist the onslaught of death, but of saving lives that may be counted by thousands; for him is reserved the happiness of seeing where before the unkept street Arab revelled in filth appear a new generation in the full vigour of health, and where disease, poverty and vice reigned supreme, to find instead temperance, happiness, and wealth enthroned. Here is true philanthropy; to those who have felt this pleasure there can be no wonder that the ancient religions of nations have little else in common were united in finding a place for hygiene; for its first dictate is respect for the rights of our neighbours. It is thus that hygiene claims a fraternity from which neither Christian, Hindu, Sikh nor Mussulman, Socialist nor Autocrat, can with a clear conscience hold himself aloof. Under the banner of hygiene, we are capable of knitting together every race and creed, because we labor for no selfish purpose—we endeavour to secure to man God's greatest blessing—health: we labor to preserve His most precious gift—life.

—:O:—

INDIAN SYSTEMS OF MEDICINE.

By BRIG.-SURGN. LIEUT.-COL. T. H. HENDLEY, C.I.E.

Residency Surgeon, Jeypur.

THE following paper was read at a previous meeting by Brigade-Surgeon Lieutenant-Colonel T. H. HENDLEY, C.I.E., Residency Surgeon, Jeypure.

When it was first suggested to me by the President of the Congress that I should write a paper on the Indian systems of medicine, I replied that I thought it would be better to entrust the subject to some one who had a wide acquaintance with original works in the ancient and modern languages of India, but it soon occurred to me that sufficient information on the subject was already available in English to render it almost hopeless to expect that anything new or of much value could be acquired in the short time at the disposal of members for writing papers. Moreover, I thought that a study of the ancient systems would be of most interest if confined to an attempt to discover whether they had succeeded or failed, and how much they had affected the present practice of medicine in this country, as well as how far they still prevent the general acceptance of modern Western medical science. It was my belief that many lessons might be learned from this enquiry, some of which at least might be of use even to physicians and surgeons who practise after the most approved modern methods. The consideration of the subject involves not only a rapid survey of the ancient practice of the medical art in India among the most educated Hindus, Mahomedans, and Parsees, as well as, perhaps, among the peasantry, but also of the treatment which the people still receive. There remain also for consideration the reactions of the different systems upon each other, the effects upon them all of religion and superstition, and lastly the results of contact with European science, and with what for a time may prove even more powerful, European quackery. I shall also have to ask whether European physicians can do more than they do

at present to increase the knowledge of their art among the people of India and to remove any prejudice against it which may exist.

The subject is so vast that in the very limited time allowed me I can only take a very superficial view of it. The history of medicine among the Hindus and Mussulmans has been treated at more or less length by numerous authorities. A list of the principal of them up to the year 1876 will be found in a small book entitled "The Vaidan and the Hakim" by the late Surgeon-General EDWARD BALFOUR. As regards the Brahmanical Hindus, the best summary is that of WEBER, the English translation of whose lectures, dated July 1878, is the latest to which I have access.

Later authorities doubtless exist, but it is hardly necessary to refer to them for my purpose. WEBER states that we find, especially in the Samhita of the Atharvav, a number of songs addressed to illnesses and healing herbs, from which, however, there is not much to be gathered. Animal anatomy was thoroughly understood as each separate part had its own distinctive name and ALEXANDER's companions extolled the Indian physicians especially for their treatment of snake-bite.

The Indians consider medicine as an Upaveda which they expressly entitle Ayur Veda. This is known only from extracts in the commentators of whom CHARAKA, who may be spoken of as a physician, and SUSRUTA, a surgeon, were the earliest and principal. The works of these writers existed before the 8th Century A. D., as, according to Ibn Beithar and Albiruni, they were translated into Arabic at that period.

WEBER goes on to quote references which presuppose an advanced cultivation of medical science, but there is nothing very definite as regards the early period. He observes, however, that the number of medical works and authors is extraordinarily large. The former are either systems embracing the whole domain of the science or highly special investigations of single topics, or lastly vast compilations prepared in modern times under the patronage of kings and princes. The sum of knowledge embodied in their contents appears to be most respectable. Many of the statements on dietetics and on the origin and diagnosis of diseases bespeak a very keen observation. In surgery, too, the Indians seem to have attained a special proficiency from whom he thinks Europeans might learn something as they have done in the case of rhinoplasty.

He thinks that "the branch of *materia medica* appears to have been handled with great predilection, and concludes that during the last few centuries that medical science has suffered great detriment from the increasing prevalence of the notion, in itself a very ancient one, that diseases are but the result of transgressions and sins committed, and from the consequent very general substitution of fastings, alms, and gifts to the Brahmans, for real remedies." He refers to the excellent commentary on Hindu medicine by Dr. WISS, and in conclusion holds that European physicians must have much esteemed the Indians down to the seventh century as Arabian medicine constituted their chief authority, and was itself much indebted to the Hindus.

In a note on WEBER's work HALL is represented as being quite opposed to the high antiquity of Indian medicine as

the sources even the most ancient texts to Arabian sources. The subject is extremely interesting, and our Indian members may add much to our knowledge of it by translating the best works.

DR. BALFOUR refers to the statements of CHARAKA and SUSSUTA and the early commentators that without a knowledge of books, coupled with practical dissection, no one can be a proper practitioner, and remarks that "these sound views afford the explanation why the ancient system of Hindu medicine was so complete, and has been so permanent in its character."

Everyone knows that the Hindus, from a very early period, have given up the dissection of bodies merely because it may occasion ceremonial uncleanness. Such prejudices did not exist in former times, and even Manu lays down that mere bathing will purify one who has touched a corpse, while stroking a cow or looking at the sun, having duly sprinkled the earth with water, will remove the defilement due to touching a dead bone.

In the present day so great is the terror of dead bodies that I have found it necessary to put up a notice in the Jeypore Museum on a case containing an Egyptian mummy to the effect that any visitor who has objection of the kind should avoid touching even the glass frame work, otherwise he might feel it necessary to undergo a long ceremonial washing. Some Hindus go so far as to think a mere look defiles. The Hindus believed in the doctrine of Humoural pathology, and considered that diseases were due to aberrations in varying degrees, of the three humours, air, bile, and phlegm, (bat, pit, and kuf). They endeavoured to restore the balance by careful dieting or elimination of the corrupted humours by means of emetics, purgatives, and blood-letting. There was a further division into sthenic and asthenic diseases which needed cooling remedies or the reverse.

The Yunani or Greek system, which is practised by Mahomedan hakims or physicians, is the second important division of medical practice in India. The chief light of this faith is AVICENNA (ABU-ALI-SUNA) who borrowed largely from Galen. His great work on the principles of medicine the Kitab-ul-Qanun-fi'l Tibb, is still a standard-book in all countries in which Arabic is known.

This system is mainly that of GALEN. Disease was due, he considered, to disproportion in the four states of the constituent elements, namely, the hot, the cold, the moist, and the dry, or to some natural condition of the organs.

He believed in the putrefaction of the humours which required elimination of the offending matter.

The Arabs borrowed from the Greeks and perhaps from the Hindus, hence the great point of similarity between the different schools, but the practices of excessive purging and blood-letting are more characteristic of the Yunani than of the Valdic system, though both believe in starving out a disease. Like the Hindus the Arabs did not practise dissection.

From the 7th to the 13th centuries the science of anatomy was stagnant. Indeed for 1,500 years, from about B. C. 300 to B. C. 200 to the year 1815, when MONDINI dissected two bodies, there was no advance in any part of the world in the knowledge of the construction of the human frame.

Both Baidis and Hakims share the prejudice so long common in Europe, against surgery, which they have left

to jarrals or rude uneducated surgeons, to barbers, quacks, and old women of both sexes.

In Europe the church was responsible for the neglect of surgery, as the clergy were prohibited from the practice because it caused the effusion of blood. This indifference was the natural offshoot of the neglect of anatomical study, because men of course, feared to perform surgical operations which might involve immediate loss of life. It is true the Hindu works named 108 marmasthanas or vital spots, but this was of no real assistance to the surgeon. The consequences of this neglect of one of the great divisions of the healing art were terrible to contemplate. The amount of torture inflicted in the rude attempts to reduce dislocations, to set fractures, and stop bleeding, to say nothing of the mischievous use of salves, and irritants to wounds of all kinds was appalling. Anyone who has practised a year or two in India can give numerous examples of such malpractices. During the past year or two I have seen an attempt to drag out the upper fragment of the femur in case of compound fracture, because it was mistaken for a piece of wood which, it was supposed, had entered the limb, and I also know that several lives have been lost from tight bandaging in fracture within my experience, in a remote part of India, the stumps of amputated limbs have been thrust into boiling oil to check hemorrhage. This was the practice in Europe before the time of AMBROSE PARE, who first used or revived the use of the ligature to stop bleeding from the arteries.

There have been many specialists for particular surgical cases as, for example, SATHYAS who practise reclinatio for cataract entirely after the old Greek method; men whose only occupation is to restore noses from the forehead, notably at Kot Kangra; lithotomists, such as a man whom I once met in Marwar who removed calculi with a rude hook and a scalpel by cutting through the rectum towards his finger with which he forced the stone forwards; or another individual, a retired sowar, an operator in midwifery cases, who on one occasion amputated the arm in a shoulder presentation and then fled. Then again there are knowing men with cattle, or blacksmiths who attempt the reduction of dislocations on human beings as they do with oxen, and dealers in weapons and armour, who think, because they know how to make arms, that they ought also to be acquainted with the best modes of treating the wounds which are inflicted by them. The Parsees do not seem to have had much influence on the practice of medicine in India, or to have taken much interest in it until their more intimate association with Europeans. They had in ancient times a firm belief in spells and charms, and probably in medical as in many other matters. After they came to India they received much more from the Hindus and Mussalmans than they gave.

According to DARMESTETER the Zoroastrians held that "sickness being sent by Ahriman, the evil principle, ought to be cured, like all his works, by washings and spells, hence the medicine of spells as most powerful of all. Although it did not oust the medicine of the lancet and that of drugs, yet it was more highly esteemed and less mistrusted."

There is one curious section in the Zend Avesta regarding the men who wished to practise the art of healing. It was laid down that those who used the knife were to operate on the worshippers of the Davaas first of all. If a

man lost three patients in succession he was considered unfit to practise the arts of healing for ever and ever. If all recovered, he might then cut the orthodox who revered MAZDA and heal them at his will. The penalty for wounding the worshipper of MAZDA before the surgeon became qualified was the same as was paid for wilful murder.

The orthodox Hindu, moreover, according to the Amrit-Sagar, was to try his skill with the ancent in the first instance on bladders.

The chapter in the Zend Avesta on fees is also interesting. A priest was to be healed for a holy blessing, the master of a house for the value of an ox of low value, the lord of a borough for an ox of average value, the head of a town for one of high value, and the chief of a province for the worth of a chariot and four. The fees for healing the wives of the above, from the master of the house upwards, were the cost of a she ass, a cow, a mare and a she camel respectively. Among those who used the knife or healed with herbs or the holy word, the last was the one who was best able to drive away sickness from the bodies of the faithful. Here again we see that to faith is attributed a higher power than the art of the physician.

I am informed by MR. VACHA, the Principal of the Maharaja's College at Jeypur, that, before his countrymen put their faith in modern Western principles, they had Baidas and Hakims of their own, the most famous of whom lived at Surat, and that certain Parsi families have at the present day the surnames of Baid and Hakim, which were adopted on account of the profession of their ancestors. In Surat and Broach there are still practitioners of the old school. Their knowledge is hereditary as is the case with that of the ordinary practitioners, both Hindus and Mussalmans, and they generally, he thinks, read Yunani books or rely upon manuscript works which have been handed down to them. Their knowledge is very inferior, though some of them become famous for the successful treatment of, perhaps, one or more diseases for which they have specialties which they are careful to keep secret, and not even to reveal to their sons.

One man at Broach was a *humbag* in other diseases, but could cure dysentery in three days, another at Surat was a famous bonesetter who rarely failed.

MR. VACHA believes that the evil spirits mentioned in the ancient writings of his people really refer in an allegorical manner to the microbes, germs, or bacteria of modern science. Similar views were put forward in a brief sketch of the Zoroastrian religion and customs which was written by MR. BHARUCHA, of Bombay, but these are only speculations which are, perhaps, not more valuable than those which declare that there are indications that electricity and even illumination by means of gas were known to SHAKESPEARE and MILTON.

There are however many notes of great suggestiveness and value in some of the old books which shew much enlightenment, as for example the following from the Khorsbod Yasht, "and when the sun rises up then the earth made by Ahura becomes clean; the running waters become clean, the waters of the wells become clean, . . . all the holy creatures become clean." All bodily secretions are regarded as impure as containing the germs of disease, and cleanliness and bodily purity

(Yaoshdathra) form one of the chief commands of the Zoroastrian religion.

It is not at all surprising that with these ideas the Parsis are very appreciative of the advantages of modern sanitation.

It must not be supposed that Baidas and Hakims have had it all their own way in India in the practice of medicine. The priests of all religions, as in Europe, have thought it their right to heal the sick, not merely by the use of spells, Charms, and texts, but by drugs, and temples have long served as consulting rooms for treatment as much of disorders of the body as of the soul. The most firm believer in a baid does not disdain to follow the advice of a mahant or religious leader, or of a Jogi or devotee whose purity of life and habits of meditation are generally held to give him some insight into the causes, nature, and treatment of disease. In like manner the most pious Mussalmans, and particularly the women, trust in the charm which a sainted *Moulei* or *Fakir* will write for a small coin, and hope that it will aid the more regular exertions of the hakim, and this is not surprising when one knows that some of the most popular practitioners amongst them have been content to feel a pulse by holding the end of a long cord of which the other extremity has been fastened to the wrist of a distant patient in the upper room of a zenana or have framed their diagnosis on the inspection of a *karura*. There are many places where there are neither baidas nor hakims, but only the village *bunesh* or purveyor, the *dhai* or nurse, whose principal avocation is to assist children into the world, and the old men and women of the neighbourhood in whom is stored up the accumulated knowledge of the simples and folklore of the country side. Such is all the medical assistance, for example, that many of the poorest agriculturists throughout the great empire of villages, and the sick among the aboriginal tribes, ever have received. Some time ago I published a list of drugs and a short sketch of the medical procedure adopted by the Bhils in Meywar, and was much struck by the resemblance of the latter to similar accounts of the medical lore of the ancients and of rude people in other parts of the world. On this subject of parallel medicine I began to make some notes, but found the study scarcely worth pursuing, that is from a scientific aspect, though of great interest from another point of view. The early Egyptian papyri, Assyrian inscriptions, old Buddhist manuscripts, Saxon leechdoms, the works of many travellers and the guides to famous shrines in India, or the lucubrations of religious leaders, most of which are full of notes on materia medica, simples, &c., all contain much the same kind of information, which amounts, in most cases, to a grain or two of wheat deeply buried in a bushel of chaff.

Perhaps the belief for charms is the most potent of all influences just now among the vast majority of the people. In a chronic case a man will devote his whole time to a sick boy. Beginning with family recipes, he will next go to the baidas or hakims and supplement their efforts with offering to the gods and in visits to their shrines, which will be tried one after the other; sooner and later, finding no help in man, he sets out with his child for the house of a devotee or *fakir* of popular repute who tells him, to do some simple, it may be even an absurd thing, or give some nameless remedy or other, or breathe upon the child, and then at

last the latter may bring the worn out sufferer to a dispensary but too late, as a rule, for any useful treatment. I think this pretty accurately represents the state of things in India at the present day. It can easily be understood that under such circumstances the quack, whether Vaidic, Yunani, or European, has a magnificent field for the exercise of his powers. I have seen very little reference to this subject but it is an important one, and is decidedly hurtful not only to the progress of European medical science in this country, but to the reputation of even *baid*s and *hakims* of whom some good men, after their own lights, although in a greatly diminishing number, do exist. A few years ago only Holloway's pills and a few well known articles of that kind were advertised or very extensively used in this country. At the present time every post brings to the educated citizen quantities of European and American quack literature, much of it, I am sorry to say, of an indecent character, but it is outdone by the so-called Vaidic remedies, which are described in nauseous pamphlets that find their way into the most remote parts of the country. The worst of it is that much of this rubbish is accompanied by certificates from men who ought to know better, and who hold diplomas from our licensing bodies. The sale of patent medicines, a large number of them really quack products, unfortunately forms part of the business of many of the medical halls in the large towns. I only mention this as a warning to practitioners, because the use of such articles can only tend to make patients, after a time, distrust the physician in whose skill as a prescriber they naturally soon lose faith.

Having given this necessarily very brief sketch of the Indian schools of medicine and of the treatment of the sick in past times as well as at the present day, it is necessary now to consider why these systems have decayed and yet still have such a hold on the faith of the inhabitants of this vast empire, and then go on to ask whether we have any lessons to learn from them and from their success so far as it goes, and also discuss what should be done to promote the knowledge of, and belief in, that which we hold to be a more rational, because a more scientific mode of practice. I think that it must be at once admitted that as long as dissection was practised, the Brahmanical Hindu surgeons and physicians were quite as advanced in the knowledge of their art as their brethren in other parts of the world. They were good observers and careful recorders of natural phenomena, but as soon as they allowed the religion of the Puranic period to interfere with them by its dictum that dead bodies were not to be examined, they lost the only means of testing their observations of true advancement.

To the same defect was due the want of progress of the *hakims*, who, when they adopted the works of Hippocrates and Galen, had a good foundation upon which much might have been built up. The onward march of medicine in Europe was prevented by the same unfortunate prejudice.

Next in importance comes the too great reliance on religious interference, on the idea which has been generally prevalent that disease is a demon which must be exorcised, propitiated or expelled by *mantras* or charms and sacrifices, or by cabalistic practices, and by the deprivation of nutriment through starvation of its host or victim. Most of us will recollect the story of the famous surgeon in the Bagh-o-Babar who opened the head of a demented youth and

relieved him by moving from the surface of his brain a centipede which was devouring that organ.* I have drawings in my possession which were taken from a work on elephants in which each disease is represented by one or more animals who torture the poor beast by sucking its blood at the effected parts or by pressing them violently, as when a snake of fearful size, for example, by coiling itself round the animal's trunk gives rise to frightful neuralgia of that organ.

The wonderful and elaborate working of the ordinary Indian mind which makes so much of details, also finds expression in medicine in the preparation of most complicated prescriptions, such for example as *churns* or powders which contain ten or twenty ingredients; or it sees a fancied connection between the shapes of certain vegetable drugs and diseases. Complicated formulæ of this kind, of course, prevent the results of remedies from being studied with any degree of accuracy, and here again we have only an evil which existed in Europe at one time and had the same results. I remember seeing an old edition of the London Pharmacopæia which was still consulted when I was a student, though it gave recipes for making the celebrated Venice treacle which contained, perhaps, three more or more ingredients, some of them of a most nauseous character. So poorly is the Indian physician paid by the great majority of his patients, in comparison with the sum lavished on feeding Brahmins and beggars, or on expensive drugs recommended by worldly wise priests, and the less conscientious members of his own profession, that it is not wonderful that men of the best powers now rarely practise medicine. There is a convenient but pretty general idea, that the good *hakim* or *baid* should be satisfied with a pittance from the State, and for the rest be content with the consciousness that his art is a charitable one which will be rewarded in another world if he is not sufficiently paid by the thanks and blessings which attend him here.

It has thus come about that much learning is not looked for in the *baid* or *hakim*, though the former is burdened with the necessity of reading all his books in Sanskrit, and as regards the latter, one may well believe the truth of the story that all the qualifications that were required in the son of a late *hakim* who lived in a great city, were that he should carry his father's staff and promise to read his books.

So much for the decay of the indigenous systems, and yet decayed as they are, and notwithstanding that educated Indians are fully aware of the immense help which is derived from such modern scientific instruments as the microscope, the stethoscope and the clinical thermometer, they still undoubtedly have much influence in the country.

To what is this due? I think to the prevailing idea that the European constitution is so radically different from the Indian that what cures diseases in the former is in the latter either deleterious or ineffective; to a belief in the systems of philosophy which accord with the Indian systems of medicine, so that the patient understands the lines of argument and practice of his fellow countrymen and co-religionists, whereas the views of the European are a mystery to him; to the fact that the *baid* and *hakim* use drugs and recommend articles of diet which are well

* The original story may be found in the *Shaj-nama* of an anecdote connected with Shuja Raja of Dhar. Translated by Pandit Vidyasagara.

known to the patient, and, therefore, in his opinion, devoid of anything which will not defile him; to the consideration which is naturally shewn for all his many prejudices and beliefs; to the feeling that after all he can have something to say in his own treatment and adopt that which commends itself to his judgment as being most likely to succeed; to the patience with which his lengthy story of his ills is heard; and lastly, I believe, to the fact that the patient generally has to do some great thing in the way of abstinence from luxuries or pleasures, and to take nauseous drugs which give him the sense of getting something for his money. With regard to religious belief and prejudice, I consulted a friend, Rao Bahadur THAKUR GOVIND SINGH, the premier noble of Jeypur, whose views are interesting and instructive. He states that the Dharma Shastras lay down that men are subject to different diseases on account of different sins committed in previous births. If the sin is trivial the disease (*karma-roga*) can be removed by the exercise of charity. They are also afflicted by changes in the three humours which are due to irregularities of diet or exposure to heat or cold. Such diseases (*dosh*) may be cured by the help of medicines. A third class of disorder arises from both causes combined, and may be removed by the practice of charity and use of drugs.

When a *baid* is called to see a patient, his first duty is to find out the cause of his disorder, and if he ascertains that it arises from any of the irregularities which have been described, he commences his treatment. Should he fail, he at once advises the use of charity, as it is evident that the disease arises from past acts of sin; should a favourable result not follow, it at once becomes clear that the man's past sins have been too great to admit of present relief. These ideas are naturally much in the *baid's* favor, as it is difficult for him to become discredited, while the priests and poor are on his side. BABU KALI PADA BANERJI, the Principal of the Sanscrit College at Jeypur, has also kindly given me an account of the education and position of Hindu physicians which I attach as a note to this paper. He observes that medicine is nowhere taught in India in the vernacular, hence much time is spent in the study of Sanscrit with which language few *baid*s in the present day become really familiar. Only books are used, there is no general practical education: pupils pick up what knowledge they can of the symptoms and signs of disease by seeing patients with their masters, from whom they also become familiar with the use of drugs. The teachers say that a knowledge of anatomy is not required in medical cases, as it is only necessary for treatment to be acquainted with the symptoms of the different diseases as laid down in books.

The Principal of the College, Mr. VACHA, also adds that the study of medicine is entirely hereditary, and the tuition confined to instruction of a son or pupil by his father or master who never teaches all that he himself knows, but always reserves one or more great secrets for his own advantage.

The foregoing remarks give us some indications of what is needful to popularize our own system.

In the first place I think we should try to lessen the prevailing ignorance of anatomy and physiology by giving

popular lectures or demonstrations which should be illustrated by the magic lantern or pictures, by exhibiting anatomical models in our museums, by encouraging the publication in the vernaculars of very simple works on the subjects I have indicated and on hygiene. These works should generally be pamphlets with rough drawings or colored pictures which the people understand better than elaborate English prints. We should take every opportunity not only in such lectures and books as I have described, but in our practice and conversation of explaining why a certain course of treatment is followed, and of assuring the people that our drugs do not contain anything which is prejudicial to the religion or caste of all classes of Indians. It is easy to shew that the best Hindus and Mussalmans find nothing in the European systems which is repugnant to their respective creeds, and that success in the practice of them does not depend upon the use of wet or dry medicines, or the solution of drugs in alcohol, or in forcing a man to adopt unaccustomed kinds of diet. At the present moment most Jains reject medicines unless they are given as dry powders, and many Hindus and Mahomedans fear that alcohol may be administered to them in some form or other. We should therefore, be careful to have no secret remedies. It would astonish many Indians if it were demonstrated to them that many of the crude compositions of their pharmacopœias are given in a far purer and therefore more exact and reliable form by Europeans. In short, it may be truly said that our system has everything to gain by publicity and discussion, whereas the indigenous ones assuredly lose when light is thrown upon them and the atmosphere of mystery which surrounds them is dispersed. As regards most of the other reasons for success of the indigenous systems which I have advanced, it is clear that we can learn much from them.

We must respect prejudices when they are not harmful, we must be prepared to give reasons for our practice, and exercise more patience and spend more time on individual cases; we must study the diet of the Indian in health as well as in sickness, and we must be careful not to prescribe the so-called patent medicines or to make too much use of routine formulae, but shew that we understand the action and combination of drugs as all Indians have great faith in medicines, and cannot understand the physician who makes light of them. Success in practice depends upon keenness of observation, upon letting nothing, however trivial, escape notice, and we may learn much, I think, in this respect from the old-fashioned conscientious *baid*, who is usually acquainted with the action of a great number of simple vegetable drugs, and is very minute in his investigations, although generally mistaken as to his interpretation of certain phenomena, such for example as the pulse. The "Amrit Sagar" says the good physician should be able to finger the pulse as a skilled performer plays upon the vina or harp.

Lastly, in my opinion, great efforts should be made to put down quackery of all kinds, especially of European origin. No quack or patent medicine should be allowed to be sold or advertised unless its composition is made known and printed on the label of every box or bottle in which it is sold. It should be easy to apply this law to European products, and then it would not be difficult to deal with the so-called Vaidic and Indian articles. Both should be

heavily taxed. A medical act should be passed by which only qualified persons should be allowed to practise European medicine, so that the art may, at all events, be presented in its true colors, and here again, I believe, there would be a strong feeling among Indians that no one should be allowed to practise as a *baid* or *hakim*, who had not passed a fair test, which in time would be gradually made more difficult.

The whole question resolves itself into a patient struggle between ignorance, prejudice, custom and superstition on the one hand, and knowledge, enlightenment, and science on the other. *Magna est veritas et prevalebit.*

The outlook is not discouraging as the increasing attendance at our hospitals and dispensaries everywhere shews, more advance in public estimation has of course been made in surgery because results are so evident, but medicine has had its triumphs, and more especially the preventive branch of it. I will conclude with only one warning, and that is, that we should be content to proceed slowly if we wish for ultimate success, bearing in mind that the habits and beliefs of ages cannot be changed in a day—no, not even in a century.

APPENDIX.

Sanskrit College, Jeypur, October 28th 1894.

DEAR SIR,—In reply to your kind note of the 18th instant, I beg to inform you that most of the notable ancient Sanscrit medical works form the curriculum of studies in the Sanskrit College here. At the Upadhyaya (Proficiency) examination in Ayurveda (Medical Science) the following are the text books:—

Nidan, the great work on the diagnosis of diseases by MADHAV ACHARYA.

Narivijnan, a tract on feeling the pulse, by RAM CHARAN DAS.

Bhavaprakas, a later compilation of medical work by BHAVA MISRA.

Paribhashapradip, a book on the Hindu materia medica by GOVINDA SEN.

Chikitsa Sara Sangraha, an ancient compilation from Charak and Susruta, by CHAKRADUTTA.

Rasmanjari, an elementary treatise on chemistry, by BHALINATH.

At the Sastri (Honours) examination the text books are:—

Bhavaprakas, as at the Upadhyaya examination.

Astangahrdaya, a work on the diseases of the heart and the whole body by BAGBHATTA.

Susruta Sanhita: chapter on the body.

Charak Sanhita: Chapters on treatment.

Rasendra Sara Sangraha, a work on chemistry, by GOPALKRISHNA.

At the Acharya (Final) examination, the text-books are:—

Susruta Sanhita.

Charak Sanhita.

Astangahrdaya of Bagbhatta.

Bhaisajya Ratnavali, a modern Hindu pharmacopoeia.

Rasendra Chintamani, the best work on the chemical or mineral drugs by RAM CHANDRA.

I may add here that these are the Sanscrit medical works generally studied also at Calcutta, Benares, and other parts of India. There are besides these many other famous Sanscrit works on medicine, namely Sarangdhar Sanhita, Atreya Sanhita, Harit Sanhita, Vira Sindhavaloka, etc., too numerous to mention. But they are not much in use at present.

2. The titles conferred here in the medical examinations are *Bishak* at the Upadhyaya, *Bhishagawar* at the Sastri and *Bhishagacharya* at the final examination. But the titles conferred in Bengal are *Kaviraj*, *Kavirajan*, *Kanthabharan*, and *Dhanvrintah*; and in the N.W. Provinces *Vaidya*, *Vaidyarsaja*, and *Vaidyachuramani*. I must mention in this connection that nowhere besides Jeypur is Hindu medicine systematically taught in the College and that everywhere else the science is taught privately by *chittan* or *naiv* *baid*.

3. To complete the whole course of medical study, at the Sanskrit College of Jeypur it takes a boy no less than a period of ten years, after which he is expected to pass the highest examination in medicine and can be said to possess a competent knowledge of the Ayurveda.

4. Charak and Susruta are, as far as I am aware, being translated into English by Kaviraj AVANISH CHANDRA VIDYARATNA of Calcutta. No other Sanscrit work has yet been known to me to be rendered into English.

5. Medicine is nowhere taught in India in the vernacular; medical education being everywhere given entirely in Sanscrit. The medical works in Hindi such as *Anrit Sagara* by Maharaja PRATAPA SINHA, of Jeypur, &c., as well as those in Bengali are never made use of by the *baid*s of even the commonest efficiency.

6. Hindu medical education is given by the *baid*s in India entirely from books, dissection of dead bodies being everywhere considered unholly. It is needless to state that the modern progress in the science of anatomy made in Europe is, therefore, almost wholly unknown to them. The Native *baid*s, however, consider themselves well up in diagnosis and treatment of diseases even without any knowledge of it; for they say symptoms of diseases are quite sufficient, except only in a complicated surgical operation, to enable the physician to deal with cases successfully. All possible care is taken by them to make the pupils conversant with the symptoms and diseases by seeing patients in company with themselves as well as to render them familiar with the herbs and drugs used.

I believe I have now put down all the information you want. Any further information on the subject you may be in need of, I will be very glad to furnish you whenever required. Yours very truly, KALPADA BANERJEE.

STRYCHNINE SUBCUTANEOUSLY IN PERIPHERAL NEURITIS.

A STODART-WALKER, Esq., M.B., C.M., advocates in favor of the hypodermic employment of strychnine in those cases of peripheral neuritis where the paralysis, swelling, anæsthesia, pain or exaggerated knee-jerks are advanced or well marked, and in which most every other medicine has failed. He cites three typical cases where variations existed with regard to the responses to electricity and to the condition of the knee-jerk, but in all of which the strychnine produced marvellously quick results and complete recovery. His method was to give three injections daily, beginning with doses of 1/10th grain and gradually increasing the strength of each injection to 1/5th grain. A little pain and some small swellings of the glands in the vicinity of the puncture follow the first few injections, but these rapidly subside, and marked improvement begins forthwith.

SOME NOTES ON SURGICAL ECONOMY IN HOSPITALS.*

By ARTHUR NEVE, F.R.C.S.

Kashmir.

It will be freely acknowledged that in hospitals economy is secondary to efficiency; and, indeed, that efficiency is essential to true economy. But efficiency may be and often is combined with waste and extravagance.

If surgeons of British hospitals had to raise and administer the funds as well as care for the patients in their surgical wards, I venture to think they would study both sides of the question, as the surgeons of the Kashmir Mission Hospital have to do. The cost of dressings has enormously increased with the introduction of antiseptic surgery. Dr. JOSEPH BELL has pointed out that while in 1854 the surgical dressings, etc., in the Edinburgh Royal Infirmary cost £286, in 1891 they cost £2,821, "an altogether astounding increase in expense."

For the sake of comparison I tabulate the statistics of the Kashmir Mission Hospital alongside those of the Edinburgh Royal Infirmary for 1891-92:—

| | E. | R. | I. | K. | M. | H. |
|-----------------------------------|-----------|---------|---------|----|----|----|
| Total operations ... | ... | 2,171 | 2,198 | | | |
| In-patients ... | ... | 4,380 | 619 | | | |
| Average residence. ... | ... | 25 days | 18 days | | | |
| Cost per patient ... | ... | £4 7 8½ | £0 7 8 | | | |
| Surgical dressings, bandages, &c. | £2821 0 0 | about | £17 0 0 | | | |
| Mortality ... | ... | 119 | 8 | | | |

It will be at once noticed that a very large number of our operation cases are treated as out-patients. The explanation that such were minor operations would not be altogether correct. The hospital suburb is always full of out patients, many of whom have religious or social prejudices against becoming in-patients. Four or five cases on whom major operations have been performed are daily brought as out-patients. Apart from the eye operations which bulk so largely (881 cases), about 650 might be reckoned as major operations.

The difference between the cost of the average Scotch and Kashmir patient is, of course, mainly due to the cheapness of food and the low rate of wages in this country, where rice can be bought for 3d per lb. So that £2 10s. a year would feed one adult Kashmiri. For the same reason wages are low, and the total cost of our seventeen dressers and servants is only £100.

On the other hand, the bedsteads, blankets, sheets, and surgical dressings have to be procured from England with the extra expense of 5,000 miles of sea and 1,500 miles of land carriage.

Obviously if we used the same surgical dressing materials in the same proportion as in Scotland, the cost of dressings for the Kashmiri patient would be greater than for the Scotch patient, amounting certainly to not less than £500 instead of the humble 217.

The expense of our surgical dressings may be thus analysed:—

Bandage cloth, 800 yards, costing £6 13s. This represents about 2,500 bandages, most of which are washed twice, and so represent about 7,500 bandages. As we apply

not less than 10,000 dressings a year, it appears that the same bandages are sometimes re-applied. The cost of washing them is about £2 a year. If new bandages were each time used, the total cost would be at least three times as great. Bandages from special cases, such as gangrene, erysipelas, or leprosy are all burnt.

Muslin for the sawdust pads, of which I give further details below, costs, with the making up, about £4. This makes about 2,000 pads, which are rewashed like the bandages.

Cedar sawdust costs about 6d. per cwt. If it has to be bought, but we preserve the sawdust of our own timber used in building. Probably 6 or 8 cwt. of sawdust, serves us for the year.

Cotton wool costs about 5d. a lb., and of the local product we use about 100 lbs. for various purposes.

The chief remaining items of expense would be Salalbroth wool, about 20 lbs., and a few packets of cyanide gauze, also a few pounds of surgical lint, with usual etceteras, protective, mackintosh, etc.

The chief requisites in a surgical dressing are that it should be aseptic, antiseptic, absorbent, comfortable, cheap, and easily applied. Of late years Salalbroth cotton wool and wood wool have become the popular and staple hospital dressings. And it may be readily acknowledged that they fulfil satisfactorily most of the chief indications except that of cheapness. Sir J. LISTER has pointed out the drawbacks to corrosive sublimate deep dressings, the readiness with which serous discharge neutralises the antiseptic properties, the over-solubility leading to the mercury being washed out, or to irritation of the skin. For these reasons the cyanide of mercury gauze, which is soft and very absorbent as well as antiseptically stable, will grow in popularity. But all these materials are expensive. Where, as in the receptions of discharges from suppurating joints, or diseased bone, or psoas abscesses, antiseptic and absorbent dressings are needed in bulk, the cost of each dressing is considerable.

If we were to replace all our antiseptic sawdust pads by Salalbroth wool the cost would be about £75 per annum instead of £4 10s. The pads are a most efficient and easily applied dressing. Muslin, somewhat close in texture to avoid the sawdust dusting through, is made into bags from 4 or 6 to 12 inches square; these bags are soaked in corrosive sublimate lotion and dried. Cedar wood sawdust (or pine sawdust) is also moistened with the lotion and dried. With this the bags are loosely filled, so as when laid flat to be from ½ inch to 1½ inches thick, according to the size of the bag. In applying them we frequently moisten the deeper layer with carbolic lotion.

The pads are admirably suited for use with the zinc cyanide of mercury. A given quantity of the mercury is stirred into some 1:20 carbolic in a tray, a few drops of aniline dye are added, and the bags are then placed flat in the tray. The sawdust in the bags should not have been medicated previously. The prepared bags may be placed to dry in a special box, or used fresh in their moist condition. It is not necessary to soak the whole bag. The dye shows which is the prepared surface. Of course, these pads can be used, and are indeed usually used with other materials. For example, if a tumour has been excised and the wound sutured, we then apply two or three

* Read before the Medical-Chirurgical Society of Edinburgh by Dr. Oathart, and sent to the Record for publication by the author.

Bags of cyanide lint (prepared as suggested by LISTER) and cover the wound with a prepared cyanide pad. If there were oozings, the pad would absorb 8 or 10 ounces of discharge, and the evenly adjusted pressure of the bag is useful, acting almost like a splint. In dressing an amputation wound the pads would be used below, where most of the discharge will gravitate, while above absorbent wool would be used.

For special cases, such as pueral abscesses with abundant discharge, extra large bags are easily provided. And for some cases similar bags, 2 feet square, are laid in the bed to protect the sheets. The pads have less drying properties than absorbent wool, which sometimes dries in such a way as to form a crust under which the discharge is pent up. This never occurs in the pads. The discharge is so uniformly absorbed that usually not a drop of matter will escape to the surface or until the entire sawdust is soaked. Here again they are superior to absorbent wool which frequently allows even a small amount of discharge to penetrate directly to the surface instead of diffusing itself.

Both the muslin of the bags and the bandages are boiled, washed, and used again. After coming from the wash they are soaked for forty-eight hours in corrosive sublimate lotion. So that there is no risk of sepsis.

These bags are used by us in padding many kinds of splints, especially for Macintyre splints. When once the preparation and use of the bags has become a matter of routine, one finds them more convenient than any other dressing for most operation cases. During the last few weeks, with several hundred operation cases from ovariotomy, hernia, lithotomy and amputations, to scrapings of ulcers or incisions of abscesses, I do not recall a single case (except eye operations and a few minors) in which bags were not used.

The two following cases may serve as examples of the application of zinc-cyanide sawdust pads:—

A. G., acute suppurative periostitis of femur; operation August 5th, 1893, drained and irrigated. Two-thirds of femur bare, and disease is of thirty days' duration, so necrosis seems probable. Applied two pads and covered with Macintosh. Wound dressed August 6th, 9th, 11th, 14th, 17th, dismissed cured August 21st. In this case there was abundant discharge, at first soaking both bags, but it rapidly ceased. Altogether fourteen bags were used at a total cost of less than 6d. With wool wool dressings this case would have cost at least 6s.

M. D., carcinoma of foot, amputation, upper third of leg. Dressed August 11th, 14th, 17th, 20th. Altogether six bags were used, a few strips, perhaps half a yard, of locally prepared zinc cyanide lint, and 1 lb. of locally prepared absorbent cotton wool. So that the total cost, including six bandages, six pads of lint, and absorbent cotton wool, did not exceed 1s.

I have at different times made experiments with the pads prepared in various ways, and then soaked with blood or serum and kept in a warm moist place. They have been kept for periods up to ten days, remoistening after a few days, and inoculating with septic pus, but without septic action, and even blood clots mixed with the sawdust became decomposed completely. These experiments require

bacteriological confirmation by cultivation tests, but they agree with the results of clinical observation.

Cotton wool in the ordinary commercial form here costs 8d. a lb. But before being suitable for use, except merely as a padding, it requires to be rendered absorbent. I should like to know a simple way of accomplishing this. After trying numerous plans I now merely have it boiled with various alkaline ingredients and soap by the washerman, after which it is carded. It will not sink in water if a pledget is dropped on the surface, but it is suitable for artificial sponges, and if bandaged on a discharging wound absorbs the discharge fairly well.

The dressing of all in-patients is invariably directed by Dr. E. F. NEVE or myself, and the assistants are taught to re-use any unsoiled portions of the old dressings in the outer dressings. Perhaps this may seem over-economy, but in careful hands with a knowledge of antiseptic surgery it is safe. It would be foreign to my present purpose to go into the subject of simple and readily adjusted forms of splints, although such are a real economy, and it is important that young practitioners should be familiarised with the use of easily obtainable and cheap appliances.

We find wooden laths and hoop iron useful, as they can be readily cut and bent to required shapes. But we also use to a large extent bracketed splints of local manufacture. A Kashmiri-made Macintyre splint costing five shillings is almost indistinguishable from the English article.

THE NECESSITY FOR AN ACT RESTRICTING THE FREE SALE OF POISONS IN BENGAL.

By SURGEON-CAPT. J. F. EVANS, M.B.,
and

ASSISTANT SURGEON CHUNI LAL BOSE, M.B., F.C.S.

Chemical Examiners to the Government of Bengal.

Introductory Remarks.—A very large number of cases of poisoning occur annually in Bengal, and as none of the safeguards against their occurrence in vogue in England and other European countries exist in Bengal, it naturally suggests itself whether, considering the difference of population, the number of cases of poisoning is excessive, and secondly, whether the number of cases of poisoning is capable of reduction.

Throughout the length and breadth of India, except in Bombay, the sale of poisons is absolutely free and unrestricted. Arsenic, aconite root, nux vomica seeds and other deadly poisons may be bought by man or woman in almost any quantity and without question. Many potent poisons such as datura, oleander, grow wild or almost so in many parts of India, so that any measure prohibiting the possession of such poisons would be very difficult to enforce.

The drugs however most frequently used as poisons do not grow wild, but can be easily purchased in any bazar in India.

In the population of every country there are some with criminal instincts ready to turn to account any opportunity that exists for the committal of crime. It is individuals of this class, who by association and habit of life

* Being a paper read at the Indian Medical Congress and sent to the Record for publication.

would come to learn the nature and appreciate the use of a poison. So long then as criminals exist, the free traffic in poisonous drugs is attended with very considerable danger to the population in general.

This being so, the necessity of placing the sale of poisons under legal restrictions has often been represented to Government by those well qualified to speak with authority on the subject. Government has however hitherto declined to take action in the matter, and on several occasions has assigned definite reasons for declining to take action.

Admittedly on all hands, the restriction of the sale of poisons in India is by no means so simple and easy as in England. Certain difficulties are self-evident, and these have apparently strongly influenced Government in its decision. Our object in bringing the matter before the Medical Congress is to invite discussion in the hope that some feasible plan of dealing with an admitted evil may be evolved.

The reason for particularising Bengal as the subject of our paper is, *firstly* that there is already in existence a Poisons Act in Bombay; and *secondly*, that complete statistics with regard to other provinces are not available. However, the few statistics that we have been able to collect with regard to the prevalence of the crime of poisoning in other provinces unmistakably shew that what is true for Bengal is also true for her sister provinces.

In our opinion, it is not only possible to restrict the free sale of poisons, but we believe also that such restrictions will also be followed by a permanent diminution of crime. We are supported in this belief by the opinions of many persons who have devoted considerable attention to the matter.

Scope of the paper.—From natural and other causes peculiar to India, the subject has many bearings. These can best be considered under the different sections into which our paper is divided.

We have arranged the matter treated in our paper under the following heads:—

- (a) Prevalence of poisoning in Bengal as compared with England and the necessity for accurate statistics regarding cases of poisoning in Bengal.
- (b) Nature of the poisoning which occurs in the province of Bengal.
- (c) Measures proposed with the object of restricting the free sale of poisons.

(a) PREVALENCE OF POISONING IN BENGAL.

Available Statistics.—The prevalence of poisoning can only be judged from the number of cases of fatal and non-fatal poisoning annually reported. At the present time in the province of Bengal, no report is available regarding the total annual number either of fatal or non-fatal cases of poisoning.

The Police Administration Reports deal naturally with criminal poisoning only, and contain no reference to instances of accidental poisoning.

The Chemical Examiner's Report is simply the record of the results of the chemical examination of viscera, vomited matters, and other articles that may be referred for examination. It does not profess to be a return even of the total suspected cases of poisoning, and affords no information as to the nature of the cases whether fatal or non-fatal, and if fatal, whether suicidal, accidental or homicidal.

The Report of the Health Officer of Calcutta and the Calcutta Police Administration Return deal with fatal cases of poisoning more in detail, but have reference only to Calcutta and its suburbs.

FATAL POISONING.

English statistics divide fatal cases of poisoning into *murder by poison, suicide and accidental death from poison.* The latest English statistics which we have been able to obtain refer to the five years 1876 to 1880. During this period there occurred 12 cases of murder by poison, 642 cases of suicide by poison and 927 cases of death from accidental poisoning. Let us first deal with the crime of murder by poison.

Murder by Poison.—As just stated, 12 cases occurred in England during the five years 1876 to 1880, or an average of '07 per million of the population in each year.

During the same period of time in Bengal the Police Administration Report shows that 94 cases of murder by poison occurred, or an average of '31 per million in each year.

Accordingly, for the period under reference, the crime of murder by poison was rather more than four times more prevalent in Bengal than in England.

The Police Administration Reports for the last five years, *viz.*, 1889 to 1893, shew a slight reduction in the number of cases of murder by poison, 81 cases having occurred, or an average of '23 per million of the population.

The crime is therefore still three times more prevalent in Bengal than in England.

Scientific evidence of death by poison.—It is admissible, we think, to refer here to the nature of the scientific evidence on which the charge of poisoning rests. First in importance is the evidence of the doctor who has treated the sick man, and that of the medical man who has made the *post-mortem* examination. Next comes the result of the chemical examination of viscera, vomited matters, stomach washings, etc. Chemical examination is often negative for many reasons; the poison may have been absorbed and destroyed in the organs of the body; it may have been voided by vomiting and the vomited matter lost, or it may have been removed by prompt remedial measures. It is partly on this account that in an enquiry as to the prevalence of poisoning that the Chemical Examiner's reports affords so little assistance. There is also another reason why the Chemical Examiner's reports are incomplete. In many instances where the medical officer holding the *post-mortem* examination finds a sufficient quantity of recognisable poison in the stomach to enable him to give a positive opinion as to the cause of death, the cases are never referred to the Chemical Examiner at all. We do not suppose this is ever done in cases of suspected murder by poison, at least it ought not to be; but it does take place in cases of suicide, the prevalence of which class of poisoning we now pass to consider.

Suicide by Poison.—As already stated, the English statistics for the five years 1876 to 1880 shew that 642 cases of suicide by poisoning occurred, or 8'55 per million of the population in each year.

In Bengal, the report of the Sanitary Commissioner shews that the total number of suicides from all causes occurring in the province during this period was 11,562 or 98'8 per million of population per annum.

For the last five years the numbers are 15,743 or 45.8 per million per annum.

The number of suicides from all causes occurring in England and Wales in the year 1875 gives an average of 65.2 per million of the population. So far then as can be ascertained, suicide is less frequent in India than in England.

We are however more concerned with the methods of suicide as practised in the two countries. In England, suicide by poison constitutes about 12.25 per cent. of the total cases of suicide, giving, as stated above, an incidence of suicide by poisoning equivalent to 8.55 per million of the population per annum. We regret to say that no returns are available for the whole province of Bengal to shew what proportion of the suicides is due to violence and what to poison; nor are all the cases of suspected suicide by poisoning that occur referred to the Chemical Examiner. Thus Surgeon-Major J. B. GIBBONS, Police Surgeon of Calcutta, informs us that out of 44 cases of suicide by opium examined by him in the year 1st June 1893 to 1st June 1894, he sent only 18 cases to the Chemical Examiner. In the remaining 26 cases, there was a sufficient quantity of opium in the stomach to enable him to ascribe the deaths to the action of the poison without the help of chemical analysis.

Suicide by poison in Calcutta.—We are not, however, without some data as to the incidence of suicide by poisoning in Bengal. For the reports of the Commissioner of Police of Calcutta afford much more accurate information regarding the occurrence of suicide by poison in the town and suburbs of Calcutta than is available for the rest of the province. Thus during the five years 1876 to 1880, 126 cases occurred or an average of 36.42 per million per annum.

For the five years 1889 to 1893, 236 cases occurred or an annual average of 68.84 per million. Of these cases 23 were due to arsenic, 167 to opium and 46 to other poisons.

Of the total cases of suicide in the town and suburbs of Calcutta, 55.8 per cent. were due to poison as against 12.25 per cent. in England. These figures also shew that suicide by means of poison is about 19 times more prevalent among the population of the town of Calcutta than it is generally among the population of England.

Is there any reason to suppose that suicide by poison is more prevalent in the large towns of Bengal like Calcutta than in rural districts, or may the state of affairs in Calcutta be taken as representing the conditions existing generally throughout the province?

There is nothing in the available statistics to warrant the latter conclusion, and there is, on the other hand, the well-recognised fact that the conditions of life in large and wealthy cities are prone to develop those mental, social and physical states which frequently prompt self-destruction. Painless methods of self-destruction are preferable to painful methods, and it is in large towns that a knowledge of the painless methods of ending life would most easily be acquired and the drugs selected for the purpose be most easily procured.

It is possible, however, that a considerable number of cases of suicide by poison occur in rural districts that are never reported to the police or brought to light in any way. Instances of suicide also occurring in the families of respectable and influential individuals are no doubt often secretly disposed of to avoid scandal.

At the present time then the available statistics afford no information as to what proportion of the total suicides occurring in the province are due to violent methods and what proportion to the use of poison.

Increased incidence of suicide by poison in Calcutta.—Some facts are however available, which go to shew that not only has suicide increased to an alarming extent in the large towns, but that the use of poison has a great deal to do with the increase that has taken place.

Hanging and drowning were the methods of self-destruction chiefly selected a quarter of a century ago. To-day in the town of Calcutta more than half the cases of suicide are due to poison, a great contrast to the conditions existing half a century ago. For in the year 1856, of 21 cases of suicide occurring in Calcutta 4 or about 20 per cent. were caused by poison, the remainder by hanging and drowning.

During the year 1856, according to Dr. WOODFORD, then Police Surgeon of Calcutta, the proportion of suicide was 1 to 2,000 of the population of the town. The proportion of suicides to the population in the town of Calcutta, exclusive of suburbs, is now 1 to 1,300, this being the average annual incidence during the last six years.

These figures shew a truly alarming increase in the crime of self-destruction in the municipal area of Calcutta and become even more significant from the fact that poison now accounts for 70 per cent. of the suicides as against 20 per cent. in 1850.

In 1865, Dr. BRATTON reported the occurrence of 41 cases of suicide at Dacca. Of these, one only was due to poison, 38 to hanging and the remainder to drowning.

It will be noted that the statistics which we are able to quote refer to only one large town in the province. Further that these statistics are advanced as evidence of the necessity for new legislative measures.

It may legitimately be pointed out that legislation, the necessity for which is based on the condition in one large town of a province with a population of 70,000,000 may not be required in the rest of the province.

To this we would reply that the existing conditions regarding the sale of poisons although possibly not productive of a large crop of suicides by poison in the rural districts, undoubtedly produce in the rural districts a great deal of other crime to which we shall subsequently refer. Further, it will be seen that the measures proposed chiefly affect the large towns.

The conditions of life in all the large towns of the province, if not exactly similar, at any rate approximate to those attending life in Calcutta.

Necessity for a medical certificate of cause of death before cremation or burial is permitted.—At the present time outside Calcutta but little is accurately known about the conditions existing in the rest of the province as regards the crime of self-destruction, nor is it probable that reliable information will be forthcoming so long as the dead may be disposed of by cremation or burial without a medical certificate as to the cause of death.

Naturally it would be preposterous in rural districts to require a medical certificate as to the cause of death before a dead body could be disposed of. It is far otherwise, however, in large towns, where medical advice is plentiful and the dead are disposed of in regular authorised places under police control.

The enactment of such a measure should form the initial step. Its operation in large towns would be distinctly beneficial, enabling the authorities to estimate the amount of crime and gauge the benefits or otherwise derived from legislative measures for its repression. The value and accuracy of returns relating to the prevalence and fatal nature of disease would also be largely enhanced by such a measure. It is in large towns also that deaths by poisoning of a non-criminal nature chiefly occur. For the welfare of the community, it is highly important that Government should be able to ascertain the number of such deaths. But so long as the dead can be disposed of without medical certificates, the accurate registration of the cause of death is quite impossible.

Death from accidental poisoning.—Death by poisoning of a non-criminal kind is usually described as death from accidental poisoning. Of such deaths 927 or 5.15 per million per annum occurred in England during the five years 1876 to 1880. It is highly improbable that anything like this number occurs annually in Bengal. The population is for the most part agricultural, and unlikely to handle poisons with the appearance of which they are unacquainted. In the large towns however, notably in Calcutta, a certain number of deaths from accidental poisoning occur annually. Thus in the municipal area of Calcutta during the five years 1876 to 1880, 14 deaths from accidental poisoning occurred or an average of 6.5 per million of the population per annum; and during the five years 1889 to 1893, 11 accidental deaths from poisoning are recorded in the same area or 3.6 per million per annum.

Certain types of cases of accidental poisoning are apparently almost unavoidable. Those cases however which arise from careless dispensing, or from the vending of drugs by ignorant, irresponsible persons, cannot be too strongly condemned.

The Bengal Municipal Act, Section 252, and the Calcutta Municipal Consolidation Act, Section 368, were framed with a view to prevent such accidents. They enact that the drugs contained in the British Pharmacopœia, if dispensed on prescription or when used by any other than a practitioner of indigenous medicine, must be prepared by a properly qualified compounder, and sold only in registered shops. That a considerable number of these same drugs, when used by a practitioner of indigenous medicine, if not dispensed on prescription, need not be prepared by a properly qualified compounder, and may be sold in a non-registered shop, and further that no restriction or safeguard of any kind shall be placed on the sale of indigenous remedies, whether contained in the British Pharmacopœia or not, provided they are not sold in a shop where British Pharmacopœia drugs are dispensed. This matter will be referred to again when dealing with the proposed restrictive measures.

NON-FATAL CASES OF POISONING.

The difficulty of obtaining any adequate conception of the prevalence of fatal poisoning in the province of Bengal has no doubt been already realised. It is in fact only possible to speak, with a certain show of authority regarding one town in the whole province, except as regards murder by poison.

Administration of drugs for purposes of theft.—In non-fatal cases of human poisoning, it is only the criminal cases that are recorded. These for the most part consist in the administration of stupefying drugs, generally datura, for purposes of theft. It is a class of crime fortunately very rare in European countries. The Bengal Police returns record 161 such cases during the five years 1889 to 1893, or an average of 46 per million of the population.

As regards other cases of non-fatal poisoning whether suicidal or accidental, absolutely no general information whatever is to be obtained. It is possible and even probable that their number is very considerable. Thus at the Medical College Hospital, 103 non-fatal cases of poisoning were treated during the year 1893, but in six only of these cases were the vomited matters or substances suspected to be or to contain poison sent to the Chemical Examiner for analysis. At the Mayo Hospital, 24 non-fatal cases of poisoning were treated during the year 1893, but in no instance was the matter referred to the Chemical Examiner by the police.*

The Bengal Administration Report shows that at the hospitals throughout the province, about 345 cases of poisoning are treated annually of which 345 recover, taking the average of the four years 1889 to 1892. The hospital records thus shew a yearly average of 345 cases of non-fatal poisoning.

Necessity for accurate statistics of poisoning cases.—Such is then the account that we are able to supply of the prevalence of human poisoning in Bengal, both fatal and non-fatal. It is manifest that the statistics are lamentably incomplete. More accurate returns are essential. It is hardly possible to suppose that legislation dealing with the free sale of some of the poisons at present in use, can much longer be postponed. The measure of the usefulness of such legislation can only be gauged by reference to the statistics of poisoning both before its introduction and after. It would be opportune therefore to now prepare the ground for the introduction of such a measure, by establishing some more accurate system for the record of cases of poisoning.

We would recommend that every case of poisoning, whether fatal or non-fatal, should be reported to the police, and further that in every case such articles bearing on the case as may be available for examination be referred to the Chemical Examiner for analysis. This is, of course, done to a limited extent in Calcutta, but it is questionable, we think, whether in other large towns of the province the proposed measures are adequately carried out. At least there are no records to shew the results of the action taken.

Suggestions for improving the statistics relating to poisoning cases.—The annual reports of the Commissioner of Police, Calcutta, and Health Officer, Calcutta, already supply more information regarding the nature and frequency of poisoning for the area dealt with by them than any other similar return.

We would suggest, however, that their usefulness would still further be increased by a slight addition to the tabular statements which include cases of poisoning. An extra column might be added to the tabular statement to convey

* We are indebted to Dr. Kolarajah Das, Registrar, Medical College Hospital, and to Dr. Manmathanath Chatterjee, Resident Physician, Mayo Native Hospital, for the following two tables upon which the above statement regarding the non-fatal cases of poisoning has been based.

information as to the evidence upon which the deaths were returned as due to poisoning, whether upon medical evidence only, chemical analysis only or both. Such information is, no doubt, already available, and would certainly increase the value of these tabular statements.

The record of accidental deaths in the police returns, both for Calcutta and the province, contains no return of the number due to poisoning. At present non-fatal cases of poisoning are not dealt with in either of the two reports, but were these cases all reported both to the Police and the Chemical Examiner, the results of investigation could be embodied in an additional table.

We are well aware that the information contained in a small tabular statement comprising a few lines often requires a considerable quantity of machinery for its accurate collection.

TABLE I.

Number of Poisoning cases treated in the Medical College Hospital during 1893.

| POISONS. | Total admis- sion. | Male. | Female. | Child. | Recovery. |
|---------------------|-----------------------|-------|---------|--------|-----------|
| Opium ... | 66 | 45 | 18 | 3 | 45 |
| Morphia ... | 3 | 1 | 1 | 1 | 3 |
| Arsenic ... | 17 | 8 | 3 | 6 | 15 |
| Belladonna ... | 5 | 3 | 2 | ... | 5 |
| Atropia ... | 2 | 1 | ... | 1 | 2 |
| Datura ... | 6 | 4 | 2 | ... | 6 |
| Cannabis Indica ... | 3 | 3 | ... | ... | 3 |
| Bhang ... | 1 | 1 | ... | ... | 1 |
| Carbolic Acid ... | 2 | 2 | ... | ... | 2 |
| Turpentine... .. | 1 | ... | ... | ... | 1 |
| Kerosine Oil ... | 7 | ... | ... | 7 | 7 |
| Strychnine ... | 1 | 1 | ... | ... | 1 |
| Castor Oil seed ... | 1 | ... | ... | 1 | 1 |
| Camphor ... | 1 | ... | 1 | ... | 1 |
| Aconite... .. | 1 | ... | 1 | ... | 1 |
| Unclassified ... | 9 | ... | ... | ... | 9 |
| Total ... | 126 | 69 | 28 | 20 | 103 |

TABLE II.

Number of Poisoning cases treated in the Mayo Hospital during 1893.

| POISONS. | Total admis- sion. | Recovery. |
|------------------------|-----------------------|-----------|
| Opium ... | 28 | 15 |
| Kerosine Oil ... | 5 | 3 |
| Sulphuric Acid ... | 1 | |
| Carbolic Acid ... | 1 | 1 |
| Camphor ... | 1 | 1 |
| Bhang ... | 2 | 2 |
| Turpentine... .. | 1 | 1 |
| Aconite ... | 1 | 1 |
| Carbonic Oxide Gas ... | 1 | 1 |
| Total ... | 39 | 25 |

That the larger towns in Bengal should make returns of poisoning cases among their population similar to those furnished by Calcutta, does not seem however to be an excessive demand. They probably are supplied with some of the requisite machinery already.

The Sanitary Commissioner's report for the province records the total suicides for the year, but the number due to poison is not separately furnished. It would be a great advantage if the numbers due to violence and due to poisons could be given separately, and if the nature of the evidence upon which a suicide is declared due to poison could also be added in an abbreviated form suitable for insertion in a tabular statement.

A similar remark applies to the Police Administration Report. No information is contained as to the evidence upon which cases are declared to be *murder by poison, drugging, &c.* If this could be added in a form not too bulky for insertion in Statement, A, Part I, the analysis of cases of poisoning would be greatly assisted.

In the same report a number of cases are returned as attempts at and abatement of suicide, but whether the attempts were made by means of violence or poison is not shown.

Prevalence of Cattle Poisoning.—Hitherto we have dealt with the prevalence of human poisoning, but we referred to the fact that the free access of poison produced a class of crime almost special to the rural districts. The crime is the poisoning of animals. It is rare in Europe but very prevalent in India. For the most part the animals are cattle, and no record of the prevalence of poisoning in Bengal under the conditions now existing would be complete, which neglected this class of crime.

During the ten years ending in 1893, 1,413 head of cattle were suspected to have died from poisoning in Bengal alone. Poison was detected in 75 per cent. of the cases.

Cattle poisoning is specially to be deprecated, as the cattle form in many instances the sole wealth of their owners. It is hoped that the introduction of legislative measures will result eventually in the abolition of this crime.

This then concludes such information as we are able to submit regarding the prevalence of all kinds of poisoning at the present time. The way has been thus prepared for the consideration of the nature of the poisoning cases which occur. Before, however, passing to this part of the subject, it will not be out of place to give a brief summary of the history of poisoning in India.

SUMMARY OF HISTORY OF POISONING IN INDIA.

The shastras here and there record cases of poisoning of kings by their nearest of kin in order to obtain possession of the throne and of husbands by their wives for reasons not very apparent. The Mahabharata records the case of BHISHM SEN, the second of the Pandavas, who was poisoned by his jealous cousin and rival Duryodhan. Although one cannot vouch for the authenticity of such cases, still they tend to shew that poisoning was practised even by the bold Aryan settlers of Northern India.

Sushruta, one of the oldest authorities on Hindu medicine, mentions the practice of poisoning the water sources of an invaded country with a view to destroy the unsuspecting invaders who might use the poisoned water. This practice is still extant; we hear of the poisoning of the water sources by aconite in Burma and Nepal at the time of the invasion of those countries by the British Army. The poisoning of water is also resorted to for the purpose of destroying fish and thereby inflicting loss on the owner

Dr. WATT mentions the use of the following plants for the purpose :—

- (1) *Strychnos Nux Vomica.*
- (2) *Lasiosiphon Speciosus.*
- (3) *Balanites Roxburghii.*
- (4) *Tephrosia Sulterosa.*
- (5) *Euphorbia Tirucalli.*
- (6) *Hydrocarpus Wightiana.*
- (7) *Hydrocarpus Venenata.*

Besides these, *Cocculus Indicus* is also largely used for this purpose.

Sushruta also mentions the use of poisons together with harmless substances as charms and love potions. He describes the various modes of administration of poison prevailing at the time, and although the practicability of some of these is questionable, it will not be uninteresting to enumerate them here. Thus poisons were mixed with food drinks, tooth powder, anointing oils, honey, fragrant substances used for cleansing the body, medicine, bathing water, essences, snuff, articles used for smoking such as tobacco, black paint and other eye salves. It is related also that poisonous substances were sometimes sprinkled over garlands, clothes, beds, armour, shoes, foot stools and seats on horses and elephants.

About two centuries before the Christian era, the whole dynasty of the kings of Magadha are reported to have been poisoned by a designing minister.

Coming to the Mahomedan age, when intrigues were common, both in the court and inside the harem, rivalry in love and political power contributed largely to the increase of cases of poisoning. The victims were either killed or deprived of intellect by the use of poisons less lethal in character.

It does not appear to be true, as stated by some earlier European travellers and quoted by CHEVREUX, that the burning of Hindu widows on the funeral pyre of their husbands originated in the fact that Hindu girls used to poison their husbands on the smallest pretext, and that this rite was enforced to put a stop to the practice.

During the earlier period of the English administration, theft by administering intoxicating drugs became frequent, and the practice prevails to this day, though to a much less extent.

The historical records give but little information as to the poisons in use in ancient times, but show that the poisoner's tradition in India dates back to a very early age.

Sufficient has accordingly been now advanced to demonstrate not only the present prevalence, but also the antiquity of poisoning in India.

The statistics quoted are evidence that poisoning is unduly prevalent at the present time, murder by poison being thrice as prevalent, and suicide by poison apparently many times more prevalent than in England, where the sale of poisons is under legal restrictions.

The conclusion is fairly logical, that those measures which have succeeded in bringing about a reduction of poisoning in other countries, may *ceteris paribus* be equally successful in India.

The fact that the conditions are not the same in the two countries has already been referred to. But it will be seen when the nature of the poisoning in Bengal is reviewed, that the special natural conditions existing in India do not at the present time exercise much influence on the nature of the poisoning which takes place. It is in fact of the very kind to be successfully controlled by measures wisely conceived and prudently initiated. A plea much stronger than the statistics of their prevalence is to be found in the nature of the greater number of cases of poisoning which annually take place in the province.

(To be continued.)

A MIRROR OF PRACTICE.

CONGENITAL FÆCAL (UMBILICAL) FISTULA.

By SURGEON-CAPTAIN PATRICK HEHIR, M.D., F.R.S.E.,
F.R.C.S.E., D.P.H. (Cantab.) I. M. S.

Lecturer on Medicine, Medical School, Hyderabad.

INSTANCES of *fecal fistula* are not so common as not to be noteworthy when one happens across them. The following case presents in addition a few features not generally met with in this morbid state.

KHOOLSUM BHI, *et. 7 years*, female, suffering from a foul umbilical ulcer, was brought to the hospital on Saturday, the 26th August 1893, by her mother, who stated that the child had suffered off and on for the last five years from an ulcer of the umbilicus. The history of the case pointed to the fact that for the first two years of life the child was comparatively well, that there was always a certain amount of swelling to the right of the umbilicus, but that during this early period of life there was never any actual ulceration, although on two or three occasions there was a certain amount of redness, and what appeared to be an inflammatory swelling.

After that age, on the first occasion of its becoming serious, the swelling gradually increased in size and eventually an abscess, about the size of a small orange, burst and set free a quantity of pus, but the wound soon healed up. Subsequently, this occurred once or twice every year, but it was noticed that for the last two years it not only attained to a larger size, but was longer in developing and slower in healing after rupture, and during the developing stage gave rise to severe distress, rigors and fever and the intervals now are seldom longer than three months, whilst the child suffers intensely during some of the attacks of inflammation.

The mother's description of the later attacks was somewhat characteristic. She stated that a swelling with redness and pain appears over the navel, extending for about one inch to the right. After this continues for three or four days, the swelling bursts and a quantity of pus, followed by actual fecal matter, would be discharged, the swelling then goes down, the opening gradually gets smaller, and finally closes; nothing being then visible till the next attack, which now came on in three or four months.

Present condition.—On examination I found a hard inflamed swelling, the inner semi-circumference of which embraced the umbilicus, whilst the outer half of the circumference extended to about 2 inches to the right and somewhat below the umbilicus. It appeared as a hemispherical protrusion above the general level of the external surface of the abdominal wall, and was exceedingly tender, but fluctuation could not be felt. The swelling appeared to extend deeply into the abdomen on the inner side of the right iliac fossa, and somewhat below the normal position of the caecum. The temperature was 100°F, the tongue foul, bowels not open for two days, the body emaciated. There was no vomiting, the patient was put to bed and an application of extract of belladonna and opium covered with a poultice, to be changed every two hours was ordered, and internally a mixture of drachm doses of sulphate of soda with $\frac{1}{2}$ of a grain of tartar emetic was given every two hours, with milk diet. An enema

was given after the fourth dose of the mixture, and the bowels then began to act freely. During the night the patient suffered from a severe rigor, and next evening the temperature was found to be 102°F. The treatment was continued for three days more, as no fluctuation could still be felt. After this, however, distinct fluctuation was felt on the fourth evening, and we were to have opened it next morning. During the night, however, the abscess burst in the usual place through the umbilicus and discharged about 3 ounces of putrid, highly offensive, faecal smelling pus.

On examining the wound thus created, it was found that there was a faecal fistula opening in the position named, which passed in a direction downwards, backwards and to the right, the whole length of an ordinary pocket case director passing into the bowels, and impinging upon what appeared to be the caecum, for the point of the director could be felt in the position of that part of the large bowel.

As I considered the case to be one necessitating a laparotomy; first, for exact diagnosis, and next for curative treatment, I suggested this to the mother, explaining what we thought to be the nature of the case. She, however, declined all operative measures, stating that I might use internal remedies and external applications. As I said it was impossible to relieve the child properly in this way, she left the hospital. I have seen two cases of this kind, and both we believed to depend upon imperfect or incomplete development, being due probably to a patent omphalo-mesenteric duct passing from the appendix vermiformis to the umbilicus. That the fistula communicates with the large bowel there could be no doubt, because the end of a long probe passed the fistula and could be felt at the right side of the caecum, and it must, of course, have passed through its whole diameter to have been felt there.

The diagnosis in the first case I was able to verify by operation which consisted in closing off the duct from the inner end of the appendix vermiformis at one extremity, and again at the umbilical end. The patient was well in a fortnight, and for the last 17 months has been quite free from the former attacks.

DEPRESSED COMMINUTED FRACTURE OF THE SKULL; TREPHINING; RECOVERY.

By JAMES R. WALLACE, M.D.,

BUNNER, a native female, aged 17 years, was admitted into the Kashipore Hospital (Terai District) at 8 P. M. on the 10th April 1879, in a state of insensibility, with an injury to the head. The following day, while passing through Kashipore in medical charge of a detachment of British troops, I was asked by the Assistant Surgeon of the hospital to see the case. He told me he suspected fracture of the skull.

The history of the patient is as follows:—Two hours prior to her reception into hospital, the woman had an altercation with her husband, who struck her with a hatchet on the top of the head. She fell senseless, bled profusely from the wound inflicted, and was brought to hospital, where, after a few hours, partial sensibility was restored, but the patient, though answering rationally, seemed very irritable when roused up, and remained in a

dull stupor all night and throughout the following day; nausea and vomiting were constant; there was frequent yawning; breathing was slow and shallow; the act of expiration was accompanied by a blowing out of the lips and cheeks; the pupils were contracted, and the pulse hard and full. I saw the patient at 5 P. M. on the 11th, and on removing the dressings applied to the head, I found an incised-looking scalp-wound in the upper parietal region about an inch and a half in length, and on passing my finger into it, felt the bone beneath distinctly fractured and depressed, to an extent that was almost incredible, judging from external appearances. The fracture extended transversely across the mid-parietal region, from one parietal eminence to the other. On the right side an area of 3 by 1½ inches of the bone was depressed about half an inch below the surrounding level. The symptoms as well as the condition of the injured parts clearly indicated both compression and irritation of the brain, set up in all probability by extravasation of blood upon its surface and spicula from the fractured cranium in contact with it. I accordingly recommended operative interference without delay. At 5 P. M. the patient was placed under chloroform, I enlarged the wound by an incision to the right side, and made another at right angles to it downwards, parallel to the external occipital crest, reflected back the flaps, and finding it impossible, as the fragments of the depressed bone were so firmly wedged in, to attain my object by means of an elevator, I applied the trephine near the anterior superior parietal angle about an inch from its apex, so as to overlap a portion of the depressed bone: this circular piece removed, the inner table of the fractured bone was seen to be detached and driven in. I now raised the bone and extracted with the forceps a sharp, triangular spiculum of the inner table, which had pierced the membranes and entered the brain; several other smaller fragments were now removed with a large blood-clot which pressed upon the meninges; a gentle stream of water was poured over the surface to cleanse it of all adherent particles; the flaps were adjusted in apposition to induce union, and light water dressing, kept constantly moist by a syphon suspended above the head of the patient, was applied; and perfect rest, with a plain unstimulating diet, were enjoined.

12th April.—At 4 A. M., before leaving Kashipore, I saw the patient, she was perfectly conscious; stated that she had passed a tolerably fair night; that her bowels and bladder had both been naturally relieved since the operation; that she felt much better, and only complained of slight headache; her skin was moist and warm; her pulse calm, and her pupils normal. I left her without disturbing the dressing on the wound, and for the notes of her subsequent progress I am indebted to the Assistant-Surgeon of the Kashipore Hospital.

12th April, 6 P. M.—Complains much of pain in the wound; no vomiting, retained the milk and soup given her. Pulse small and quick; skin hot; tongue slightly furred; no bleeding from the wound.

13th April.—Headache continues; slept well; bowels inactive; tongue drying; pulse quick; no change in wound. Ordered five grains of calomel; milk diet.

15th April.—Pain in wound less; a thick purulent discharge from wound; tongue clean; pulse full; skin

warm; bowels evacuated twice yesterday and to-day. Complaints much of thirst; refrigerant drinks given; carbolic dressing applied to wound.

16th April.—Feet much better; wound looks healthy; some small granulations appearing; discharge continues; no headache; bowels active; appetite good. Repeat dressing and diet as before.

18th April.—Slightly feverish to-day; thick purulent discharge from wound; some small particles of necrosed bone have come out with the pus; bowels not moved; calomel given; wound well syringed with weak carbolic solution; continued dressing.

25th April.—There has been more or less fever the last few days, but the wound looks healthy, the flaps have not contracted; a portion of the contused scalp has sloughed away to a small extent near the centre of the wound, but this point is covered with healthy granulations; discharge of pus continues, but very scanty now. Repeat dressing, drinks and diet. No other untoward symptom manifested itself, and the case progressed favorably; the wound was quite healed ten days later, and the patient only slightly debilitated, was discharged from hospital cured on the 9th May 1879, or twenty-eight days after the operation.

Remarks.—This case seems clearly to illustrate the three conditions of the brain which often follow each other in a quick succession of stages, in injuries of this nature, namely, (a) *Concussion*, or stunning dependent upon commotion or sudden disturbance of the cerebral mass, noticed immediately as the blow was received; (b) *Compression*, marked by a gradual retrogression to unconsciousness, after the patient has rallied from the primary shock, and dependent upon extravasation of blood beneath the cranium, either within or external to the membranes; (c) *Irritation*, a condition which usually precedes inflammation of the encephalon and meninges in these cases, when a spiculum of bone is driven down and presses upon the cranial sac and its contents.

The *expectant treatment* advocated by ABERNETHY, SIR ASTLEY COOPER, DUPUYTREN and others, it is evident could not have been effectual in this case, for not only would it be contra-indicated by the extensive depression of the bone which was present, but injury to both the brain and its coverings, as revealed by the operation, amply justified the measure resorted to. Failing this, inflammation would have been an inevitable sequence. While at the Calcutta Medical College, I remember to have seen two such cases as the one I have recorded, both in the late Professor GAYER's wards. In one treatment was delayed in the hope that urgent symptoms would not manifest themselves, but the patient died from encephalitis; in the other instance the extent of the fracture was all that seemed to justify surgical interference, no urgent symptoms were present; DR. GAYER trephined, and the patient made a rapid recovery.

THREE CASES OF SEVERE SUICIDAL THROAT-WOUNDS: RECOVERY.

By ROGER G. S. CHEW, M.D., C.M., M.S.C.,

Calcutta.

IN January 1877, I was attached for duty to the Allahabad Fort Hospital, where one morning Private K.—of the—Fusiliers, was brought into the ward in an unconscious state with his tunic saturated with blood. Examination showed two incised wounds, the superior cutting obli-

quely through the upper half of the pectenus *Adami* and about 2.5 inches long, while the inferior wound which was 3.25 inches long, cut through the trachea.—0.25 inch below the larynx and lacerated the oesophagus. The teeth were clenched, pulse weak, and at every expiration, air bubbles and blood were forced through the lower wound; but the large vessels of the neck were not injured by the razor with which the cuts were inflicted. No reason was alleged for this attempt at *felo de se*. After washing with boracic lotion, the edges of the wounds were brought into apposition and kept *in situ* by narrow strips of adhesive plaster crossing each other at short intervals. No sutures were applied, and the patient was kept quiet in bed. His temperature rose to 105°F that evening, and there was some delirium; but next morning febrile symptoms abated and he made a rapid recovery; the wounds healing by first intention. For the first four days, and until there was distinct evidence of healing by first intention, the patient was fed by allowing drops of beef-tea to trickle down his throat every 4 or 5 minutes, as he refused to be fed by the stomach pump tube; and after the sixth day he was able to swallow fairly large quantities of fluid with very little pain and trouble.

Case II (1879).—An Afridi, in consequence of a quarrel with a relative, ran a fish-knife through his throat, making a fearful gash six inches long and running transversely with jagged edges from the middle third of left lower jaw right down to the sternal end of the clavicle, but luckily the large vessels were uninjured. The patient being intensely weak from loss of blood, and symptoms of lung complication being present, he was not chloroformed. A tracheotomy tube was passed into the windpipe, bleeding was stopped by torsion of the points, the wound freely irrigated with 1 in 1,000 carbolic acid solution, and a very long narrow strip of gauze having been placed plug-wise inside the upper trachea; the edges of the wound were brought together and herring boned with carbolic catgut sutures—one end of the gauze being brought outside the wound to act as a drainage tube—and the whole capped with a gauze pad. Delirium with fever supervened and the patient who was unconscious for nearly three days, was fed by enemata in half ounce doses every hour, and given subcutaneous injections of quinine in the intervals of the febrile paroxysms. The plug was removed on the twelfth day and fever abated on the 25th, when he was fed *per os* with liquid food. He made a complete recovery in five months, but the tracheotomy tube was not removed till nearly two years afterwards, when a plastic operation became necessary to close its site of puncture. This tardy recovery was due not so much to the severity of the wound, but to the insanitary surroundings of the patient who lived in a village near Junrood on the Afghan frontier and refused to be brought into cantonments where he would have had better attendance.

Case III.—An Egyptian soldier, name unknown, was shot through the loins at the moonlight raid on Kassassin (Egypt 1882) and the agony of his wound—though nothing vital was injured—prompted him to put an end to his sufferings by thrusting a large pen knife through his throat and forcing the blade outwards and away from him. He couldn't blow his brains out as he had no ammunition left. The left sternocleidomastoid was cut, and the back of the larynx could be seen. A gaping wound which was 3.5 inches long by 4.25 inches broad. Antiseptics and sutures not being available, the sand, dust, &c., were washed out, the cut surfaces were brought in apposition and held in place by adhesive plaster, while the wound in the loins was washed with canal water and plugged with lint soaked in carbolic oil. (1 in 60). To the surprise of every one the man made a complete recovery of the throat wound in three weeks, and of the bullet wound in as many months.

Indian Medical Record.

18th February, 1895.

DR. ERNEST HART ON MEDICINE AND ITS PRACTITIONERS IN INDIA.

THE excellence of the address delivered by DR. ERNEST HART on the last day of the Indian Medical Congress meeting of 1894 is admitted on all hands. His acquaintance with all current opinions and with all progress made in medical matters with which the profession in this country is particularly concerned, and his easy and impressive style of putting these matters before his hearers have received general commendation; and his unique opportunities for keeping himself well abreast of the times in professional concerns, is great justification for the assertive and authoritative stand which he took from time to time in the course of the address. It would have been better, however, had DR. HART confined himself "to the more engrossing scientific and practical questions which concern the future of medicine and the welfare of the seething masses of humanity entrusted to our care;" for with regard to these, as we have said, he may be accepted as an authority; but he was particularly unfortunate in his remarks on those subjects which are not "free from polemical and personal differences of opinions," as he said of the conditions and history of the profession in India. These remarks have much of the usual characteristics of the globe trotter's collection of contributions furnished and received from interested sources—PREJUDICE in authority. With all the professional and intellectual acumen of our respected friend DR. HART we fear that his faith in some of his educators has been too great, and he has been evidently regrettably beguiled into statements and opinions in connection with the medical services of the country which, to say the least, are not strictly correct or which cause false impressions. However much DR. HART has endeavoured to make his utterances appear free from all taint of bias or prejudice against any section or sections of the profession in India, there are a few inconsistencies which we are at a loss to understand and explain, and a few statements which shew that he has been incorrectly informed, wrongly impressed, or that he has unfortunately misunderstood his informants. For instance DR. HART remarks that "the service of Government is open to all who can satisfy the conditions and requirements laid down by Government." This is far from correct. It is true, with regard to the Indian Medical Services only, and this only after eliminating, as we do now, the rumoured attempts to exclude Indians, as far as possible, from this service even. In the civil departments, however, of the State non-service men are positively kept down. They are scarcely ever admitted to any of the higher offices; and this, notwithstanding the fact, admitted by DR. HART himself, that these non-service men are "a considerable and increasing number of those who proceed to Britain for the purpose of medical study, and return to India with British diplomas and degrees;" and that they comprise a large number of "British licentiates and graduates who have proceeded to India for the purpose of earning a livelihood." Even with the fullest

compliance with all the conditions and requirements demanded by Government, a non-service man *cannot*, but in the most exceptional instances, get a college professorship, a chemical examinership, or any Government appointment worth having. Is there not a positive reservation of these appointments for men of the Indian Medical Service? DR. HART, no doubt, wishes to give the Government full credit for "Fair Play," and perhaps thinks that everything is fair and square inasmuch as the Indian Medical Service, for which these appointments are reserved, is thrown open to all creeds and classes alike. He appears to lose sight of the fact that, to gain an entrance into the I. M. S., one of "the conditions and requirements laid down by Government" for the obtaining of these appointments is to create a reservation of appointments for a staff of highly paid military officials to the unjust exclusion of those who "return to India with British diplomas and degrees" and of those "British licentiates and graduates who proceed to India for the purpose of earning a livelihood." Moreover, is it not next to impossible for men of the purely civil medical services of the country, possessed of full British qualifications, and with all the advantages of service and of experience, to obtain any other but the subordinate or the less important appointments of the State? If then in saying that "the service of Government is open to all who can satisfy the conditions and requirements laid down by Government" DR. HART was cognizant of and fully considered the fact that admission into the I. M. S. is a *sine qua non* for most or all of the most important and coveted appointments, he appears to view with complacency an injustice inflicted on a very large section of the profession in India.

We are obliged to make rather a lengthy extract from DR. HART's address for our next consideration. Taken in connection with a great deal that is said and urged later on in his address, the extract appears full of incongruities and to betray a national prejudice. No one who is well conversant with the medical organisation of this country will, after a careful perusal of DR. HART's address, look upon our much-respected and learned friend as an Oriental Solon; nor can DR. HART expect to have his utterances in the matters in question regarded as coming from one who is an "authority" on the medical administration and working in India, however much his opinions on purely scientific questions are to be respected. "It has been urged," says DR. HART, "that it is the duty of the Government to utilise more largely indigenous medical agencies, and it has been argued in some parts of India, that an equally efficient and considerably less expensive medical service, more especially for civil duties, can then be obtained. The cry of 'India for Indians' has been raised in this connection. It is to be noted, however, that this cry does not come from the Indian members of the profession, but from a few non-official Anglo-Indians, and much feeling has arisen in this connection. *Learn to have patience. Governments and such like institutions move slowly.....* The Government must be trusted for knowing the purposes for which its servants are required, and adopting the best means of obtaining these of the best quality and at the cheapest rate." We have taken the liberty of italicising a few portions of the foregoing, which perhaps contains

admirable advice; but Dr. HART is evidently no believer in his own preaching. If our worthy friend had such implicit faith in our Government as to feel that it "must be trusted for knowing the purposes for which its servants are required, and adopting the best means of obtaining these of the best quality and at the cheapest rate," why did he worry himself unnecessarily in pointing out the "needs of the Army Medical Department," the formation of a Royal Medical Corps, the inequality between the treatment of the Medical Staff and of other corps in the matter of Government grants for messes, the necessity for replacing the Army hospital native corps with the infinitely more expensive medical staff corps, &c.? Wherefore, all these suggested expensive innovations Dr. HART, when the statement that the Government must be trusted for knowing its own purposes and how to effect them most cheaply according to your own saying, may be accepted "as a true representation of the circumstances of the case"? Why not "learn to have patience as Governments and such like institutions move slowly" as is your firm conviction? To us the whole advice so paternally tendered by Dr. HART to Indians reads as an appeal to Indians not to push forward their just claims, lest the Government may come to recognise the efficiency and cheapness of indigenous medical agencies. It reads very much like "withhold your claims yet a while Indians; we Britishers may be deprived of much which we, by special favor, enjoy; and besides we would much like to have a little more." And this cry of 'India for the Indians,' he it noted, is the result of the unwarrantable interference of a *few non-official parties*. We would like to know at what pains Dr. HART has been to determine "that this cry does not come from the Indian members of the profession." We would certainly have thought that any body with the most ordinary acquaintance with Indian affairs knows well that 'India for the Indians' has been the cry of the rapidly increasing educated Indians throughout the length and breadth of the land, not only in respect to each and every branch and department of the public services. Flagrantly erroneous statements, such as we are now considering, detract much from the merit of Dr. HART's address, and betray a susceptibility to false tutoring, or an easily-imposed-upon credulity; and it is hard to say how far these have influenced all the other opinions which he has so authoritatively expressed. Here is another assertion occurring at the tail end of the address, which makes this veteran medical journalist appear very gullible and credulous. "A second obstacle to the successful cultivation of medical research in India is the over-loading of the medical officer with clerical work of the most menial character, and which might be very well and much more economically done by a less highly paid and less valuable officer. I have been told that the case books in many instances tend to be filled with the cases of patients requiring extra diet and not with important cases. I understand that every insignificant case to which an extra egg, or such like, is presented *must be written out in full*, while perhaps some cases of medical interest may be neglected. This is a sad and surely avoidable waste of time and energy, and so throughout the whole of his duties perpetual writing and red-tapism, medical officers tell me, they have to spend more time in their office than in their

wards." The italics are mine. The whole of the foregoing extract displays a very confused idea of the matters to which reference is made. Medical officers spoken of as being hampered with menial clerical work. Are the medical officers men of the I. M. S., or M. S. or of both, thus mercilessly piled with clerical labor? We will try and enlighten Dr. HART on these matters. Medical officers of the army in civil employ as District and Civil Surgeons, have no doubt varied duties and heavy responsibilities; but they are in all instances provided with clerks, and the only writing work that they themselves do is the keeping up of their cases. This surely cannot be regarded as "clerical work of the most menial character;" and in the case of these officers, the regulations demand that *all cases of interest* should be recorded, and the diets or extras given have nothing whatever to do with the necessity or otherwise of a case being taken or recorded. This ruling applies only to station hospitals, and Dr. HART's remarks are evidently made from information received regarding the duties of officers of the medical staff in station hospitals. But even with regard to these, what Dr. HART has been told and what he understands are open to much correction. To refute what Dr. HART has been told and what he understands "that every insignificant case to which an extra egg or such like is prescribed, *must be written out in full*, while perhaps some cases of medical interest may be neglected." We invite Dr. HART's attention to para. 685 A. R. I. Vol. VII, which says: "Every important case in hospital, and all such as are in receipt of extras (other than effervescing liquids, drinks and eggs) will be recorded in the case-book, &c." This surely is absolutely the reverse of what Dr. HART has been told and what he understood to be the case. As a matter of fact, medical officers of station hospitals are careful in avoiding to prescribe extras which involve case-taking, except where such extras are absolutely necessary for the well-being of the sick. We need not minutely detail the clerical work of medical officers of station hospitals, but irrespective of the office work, for which the senior officer in charge is responsible, and which is carried out by a clerk, all the clerical work that the other medical officers do, consists almost altogether of the prescribing of diets to the few patients in their charge, keeping up the records of a few important cases, and of their weekly sanitary report of the barracks. None of these surely is of a non-professional or of a menial nature. If Dr. HART had been at the least pains to see and judge for himself, he would have known that a working day of an officer of the Medical Staff in India consists of about *three short hours* and in many—very many—instances, of *infinitely less*. If, under the circumstances, these medical officers cannot find time for research and investigation, there must indeed be "a sad and surely avoidable waste of time and energy," which certainly is not due to "perpetual writing and red-tapism." We feel sure that the most serious and matter-of-fact officer of the Medical Staff in India would not be able to suppress a smile in perusing Dr. HART's doleful representation of this "overloading of the medical officer with clerical work of the most menial character." We fully agree with Dr. HART in that this work "might be very well and much more economically done by a less highly paid and less valuable officer," by the Medical Staff of station hospitals being composed of

better paid Military Assistant Surgeons, under one member of the Medical Staff, of service and experience, as a consultant. With the Medical Staff of a station hospital composed of an experienced Consulting Surgeon in charge, with Military Assistant Surgeons as co-adjutors in the treatment of the sick, and an efficient Army Hospital Corps, European, Eurasian or Native, the military medical needs of the country will be thoroughly and amply met. Dr. HART is justly proud of his position as Editor of the *British Medical Journal*—a position in which he enjoys, as he asserts, "what are perhaps exceptional opportunities of gauging the times, of learning what is being done in things medical all over the world, and of perceiving perhaps what is the best thing next to be done." In many instances, as we have shewn, he has not taken sufficient advantage of those exceptional opportunities, and "the best thing next to be done" by Dr. HART, is to learn not to believe what he is told even by medical officers, for some of these may play him false, especially in the matter of "the Medical Profession in India: its position and its work" (clerical and professional) but for him to see and judge for himself in these matters.

—:0:—

THE INDIAN PASTEUR INSTITUTE.

As the opposition of the Bengal Branch of the Anti-vivisection Society to the proposed Indian Pasteur Institute has prevented some from subscribing towards the Institute, Surgeon-Colonel HARVEY, in a paper read at the Indian Medical Congress, endeavoured to shew that experiments on living animals are not only justifiable but necessary, and that donations to the proposed Institute may be given with a clear conscience. Dr. HARVEY made two divisions of the subject: (a) vivisection proper, which alone involves cutting operations on living animals; and (b) experiments on animals not involving cutting operations. The first of these involved the death of the animals; the second involving temporary pain or discomfort only. The opponents to vivisection wrongly include all the foregoing under the term vivisection. He summed up the opposition arguments to be (1) that animals have rights as well as men, and that one of these rights is to be saved from cruelty. (2) That the experiments lead to little or no useful or practical result. (3) That even if they did, the cruelty which they involve makes them unjustifiable, since man has no moral right to inflict cruelty for his own advantage. (4) That the experiments have a demoralising effect on those who perform them. (5) That it is a hellish practice and goes hand-in-hand with atheism.

The scientific arguments are: (1) that the experiments are necessary for the advancement of knowledge, and that this necessity is recognised almost without exception by the medical profession. (2) That they have in fact "been of inestimable service to man and to the lower animals, and that the continuation and extension of such investigations are essential to the progress of knowledge, the relief of suffering, and the saving of life. (3) That they are conducted under Parliamentary restriction without cruelty, and with the least possible suffering. (4) That the statements of the anti-vivisection party are inaccurate, exaggerated, and misleading. (5) That suffering and

sacrifice are facts in nature which . . . can effminate, and that the rights of man are superior to those of animals. (6) That the experiments have no demoralising effect on those who perform them.

Dr. HARVEY was of opinion that the term vivisection should not be applied to experiments performed under chloroform in which the animal is killed without recovering its senses, and which involve no pain; or to the killing of animals by poison, or snake-bite; or to the feeding of them with particular varieties of food, &c. Again the profession and physiologists give to the word "cruelty" the accepted English meaning, *viz.*, "an act which causes extreme suffering without good reason." "A disposition to give unnecessary pain." The experimentalist therefore cannot be charged with cruelty, as the experiments are not unnecessarily undertaken, and they are productive of good to men and animals. The anti-vivisectionist however takes cruelty to mean "the voluntary infliction by a moral free agent on a sentient being, of severe pain, not beneficial to the sufferer, and not authorised by justice." By thus throwing the dictionary out of the window and adopting a new ethical standard the anti-vivisectionist denounces the experimentalist as cruel. It was important, Dr. HARVEY said, to keep this in mind. Considering the objectors' arguments then *seriatim*, he said that physicians and physiologists maintain that man has dominion over animals when good reason can be given for subordinating their rights to his. As to the objection that these experiments lead to little or no useful result, the testimony of the medical profession should outweigh the opinions of others: and with very few exceptions, the profession says it has been helped by these experiments. Resolutions to this effect were passed at the British Medical Association General Meeting at Nottingham in 1892; the International Medical Congress at London in 1881; and the Church Congress at Folkestone in 1892: while the Royal Commission appointed at the instance of the objectors in 1875, concluded that the greatest mitigations of human suffering have been in part derived from these experiments. The circulation of the blood, the physiology of respiration, the functions of the spinal nerves, of the liver, and thyroid gland, the localisation of the motor areas in the brain, &c., have all been learned from the Baconian principle "interrogate nature." Physiology deals with life, and vital phenomenal experiments in that science must necessarily be on living creatures, since death puts an end to living functions. In objecting to such experiments, physiology is condemned to stagnation, and an end is put to progress in medicine and surgery, which are founded on a knowledge of physiology and pathology. With regard to the third objection, *viz.*, that even admitting the utility of the experiments, they are unjustifiable on account of the cruelty involved, as man has no right to inflict cruelty for his own advantage. This must, if true, be accepted universally and always. It leads by strict logical necessity to forbid the killing of animals for food, and puts an end at once to practices now universally followed by man for his convenience, sport, or profit, the gratification of his personal variety, or his bodily appetites. In angling, in riding a fox to death, and in castration, which is vivisection of the most painful kind, man constantly inflicts severe pain not beneficial to the sufferer. Those then who drive

geldings and eat capons are participators in offence. All these practices deserve to be decried as cruel just as much as the physiologist's experiments. Has not a mosquito rights, is a bug not a sentient being? Are their sufferings beneficent to them? Every pious Hindu, who has ever seen a cat killed, shudders at the sight. The same applies to anathema. With the clubbing to death of seals, the destruction of unoffending birds when feathers are to be worn, the use of painful gag-bits and bearing reins, the jinxing of fowls, the subjecting of geese to grave disease, boiling lobsters, &c., all mankind, according to the antivivisection definition of cruelty, are guilty as well as the vivisectionists. These latter are doing what all mankind are constantly doing, viz., subordinating the interests of individual animals to the general welfare of humanity and of animals themselves; and their action is justified, both by necessity and by ethics. Justifying themselves they justify also all such actions of other men as do not involve wanton, unnecessary and objectless suffering.

As to the demoralising effect of the experiments on those who performed them, Dr. HARVEY remarked that there were no keener fishermen than the clergy, and yet we did not find them demoralised or converted into base and brutal monsters. Dr. HARVEY was proud to number among his friends several vivisectionists, and knew them to be humane and honorable men. Oppositionists, say nothing or little of the object of the experiments; the use of anaesthetics is either not mentioned or brushed aside as not really abolishing pain; results are sneezed at as useless; and symptoms occurring in insensible animals are accepted without question as evidences of acute agony. The opposition of anti-vivisectionists is based on untrue and exaggerated statements.

Dr. HARVEY considered a Pasteur Institute necessary for India, and asked the Congress to help to convince the public that such was the case by unanimously affirming the following resolution:—"That a Pasteur Institute for India is essential to the advancement of science, the investigation of Indian diseases in men, animals and plants, and the treatment of diphtheria as well as of those bitten by rabid animals." This resolution was carried unanimously.

Professor HANKIN of Agni, in seconding the motion, said that, under a license, he carried out in England perhaps a larger series of vivisections than were done by any one else at the time in England, and he did not believe that he ever in his experiments gave a single animal more trouble or pain than is given to a child in vaccinating it. Mr. HANKIN said it is to be noted that such trivial operations as taking a minute drop of blood from a rabbit's ear are of the kind most prized by antivivisection agitators, as they are of the kind done without the aid of anaesthetics. These agitators went round the country parading such experiments as examples of the horrible sufferings inflicted on animals by physiologists; and by such action the anti-vivisectionists have become thoroughly discredited at home; and Mr. HANKIN would be sorry if any one in India thought it necessary to give much attention to anything they say.

It is rumoured that the worthy President of the Congress is to be honored with a C. S. I., and the two able workers of the Hyderabad Chloroform Commission are to obtain the decoration of C. I. E. in the next Birthday Honors List. Certainly we hope the rumour is well founded, as fitter recipients for such honors, could not be found.

COMMENTS AND NEWS.

FEIGNING OR MALINGERING.

FEIGNING, for which there are several motives, and which is frequently resorted to, occurs in three forms:—(1) *Entire*, where all the symptoms are merely presented. (2) *Partial*, where the symptoms of any disease or injury already existing is exaggerated; and (3) *Artificial*, where the disease or injury or symptoms simulating them are produced by the patient for the purpose of deceiving. As feigning is but a species of fraud and the exposure of fraud is a public good, Dr. H. C. FAIRBROTHER points out the humiliating position of the medical man who has been victimised by the malingerer, and tender certain general rules which aid the investigation of malingering. (1) *Moral character if it cannot bear scrutiny or has a tendency to falsehood* is of great aid in the detection of feigning. (2) *Motives*, whether pecuniary gain or profit or advantage or exemption from some irksome duty, may not accrue to the party feigning. (3) *Physical condition* will excite suspicion if the color of skin or the features are not indicative of the serious illness or injury that the patient alleges to suffer from, or if his general appearance indicate perfect health. (4) *Expression of countenance* is an important factor towards detection, and so is *manner of answering*, as a person feigning will seldom or never look his medical examiner in the face or answer his questions fairly, clearly or squarely. (5) *Want of consistency*. Malingers not, as a rule, being medical men are apt to over-act or over-do the symptoms of the disorder feigned. Though the diseases simulated are legion, insanity, paralysis, convulsions, stiffness of joints and defect or loss of special senses form the most common roll of alleged affections; PAIN forms the *stock-in-trade* of the malingerer, because pain is the most easy to complain of and the hardest to contradict, yet pain is such a dreadful reality that it cannot be long hidden if it exists and pretend pain, like murder will discover itself when the culprit least expects it. Pain itself is complained of under three headings:—*1st.*—What the patient alleges, and you can't at once contradict except his countenance give him the lie, and you can manage to catch him unawares by secretly marking the spot and jabbing at it when he does not expect it. *2nd.*—What is elicited by pressure, palpation and physical examinations, and which, if simulated, can be detected by the above method; and *3rd.*—Pain on motion of the body, and more particularly of the joints; but when the patient's expression of countenance betrays or careful watching of the culprit will detect or the man may over-do his symptoms by unwarily raising or moving the limb to a height or in a direction that he said he could not achieve.

DR. GRAY AND THE JAMSHETJEE JEEJEEBHAY HOSPITAL.

PUBLIC opinion having been rather severe on the late outbreak of cholera at the Jeejeebhoy Hospital, which was alleged to be "ill-kempt in some essential respects," Dr. WELLINGTON GRAY comes to the rescue by saying that year after year the grave sanitary and structural defects of this hospital had been made public, while the hospital authorities had done all that, under the circumstances, they could do to prevent infection and preserve asepsis, but it was no fault of theirs if the walls, floors and the location of the hospital rendered conditions favorable to the invasion, propagation and preservation of disease germs. Besides this he had forwarded to the Surgeon-General several complaints and suggestions, some of which had in course of time been acted upon and the others for the most part had been pigeon-holed. Why these letters were not taken prompt notice of does not transpire; but a contemporary submits that a great many more have been ignored in pursuance of the principle that one of the crowning merits of a Surgeon-General is to run his hospitals cheaply, as economy is nowhere more appreciated—and sometimes rewarded—than in the Surgeon-General's Department.

WANTED: A STRINGENT PHARMACEUTICAL ACT FOR INDIA.

We quite agree with our contemporary, *The Times of India*, in his remarks on the necessity for legislative enactment to prevent the sale of bad medicines, and the issue of badly or wrongly dispensed prescriptions. The bazaar dispensers of doctor's prescriptions, if not drawn, as our contemporary asserts, from a class very little above a coolie or a table boy, certainly in the vast majority of cases know little or nothing more of drugs than a very imperfect knowledge of their names. Order and arrangement of their stock-in-trade are matters of which these dispensers are dangerously ignorant; and the careless way in which poisonous and non-poisonous drugs are placed in juxtaposition, makes us quite sure that the bulk of the Indian public, whose safety in the matter of drug-dispensing is the scantiest conceivable, has infinitely more to thank Providence and their guardian angels for, than they throw off. The chances of wrong administrations and dispensings are almost countless, and it is useless for us to try to enumerate them. With dispensers of this kind (particularly if they are proprietors too of these medicine shops) drugs are never considered as too old; and their deterioration, however advanced, does not stand in the way of their being got rid of in the form of mixture, pill or powder. The purchasing public is, no doubt, a great deal to blame for this pitiable state of affairs, for it considers nothing more than the cheapness of the make-up, or we should more correctly say, the low charge for the dispensing of a prescription. It inwardly admits but practically ignores the fact that in dealing with these ignorant compounders the chances are that it is throwing away its money on dangerous or worthless concoctions.

HOSPITALS FOR GENERAL PRACTITIONERS.

The Medical Times and Hospital Gazette makes, what it believes to be a very feasible suggestion for general practitioners protecting themselves against the pecuniary losses they sustain by public hospitals and ignorant and inexperienced chemists, depriving them of patients who can well afford to pay for proper medical attendance and advice. Our contemporary thinks that it is useless to appeal to the State for help in these difficulties, and that general practitioners must work out their own professional salvation; and that the simplest and best way of doing this is for general practitioners to combine and open hospitals to be managed by themselves. A number of practitioners working in a given district should combine and act both as the committee of management and also as the medical staff. The suggestion appears to us to be quite good and practicable; and we would even predict that in India general practitioners would receive the support of Governments in this suggestion being acted upon. It is likely that the Government will be glad to be relieved of some portion of its expenditure on hospitals and dispensaries; and it may be found willing to make over some of its buildings and equipment, under certain conditions, to reliable and well-organised medical staffs. This will be a means of teaching the people to help themselves in the matter of medical relief. We strongly commend the suggestion to the careful consideration of our financially better circumstanced brethren.

THE PARSEE MATERNITY HOSPITAL, BOMBAY.

The Bombay Esplanade presented quite a gala appearance on the 12th ult., and a huge assemblage of Europeans and Natives was present when LORD HARRIS threw open the *Parsee Maternity Hospital*, which is destined to be of inestimable service to the Parsee community of Bombay, and does no little credit to DR. T. B. NARIMAN, that indefatigable hygienic reformer and those of the community who largely responded to his call for contributions to erect a hospital where Zoroastrian progeny may be brought into the world without endangering the lives of their mothers by general septic invasions, the

(hitherto) almost invariable consequence of the time-honoured but rather perverse practice of badly ventilated and ill-lighted ground floor, lying-in and sick rooms for Parsee women, instead of providing them with airy upper rooms. LORD HARRIS cordially congratulated the Parsees for the spirit of self-help that led to the construction of this hospital; and DR. NARIMAN, while thanking his community for the valuable assistance rendered him, pointed out that the erection of the hospital is only the thin edge of the huge wedge of reformation that is needful for correcting the pernicious perversions of the Zoroastrian teaching, and saving the people from the wholesale murders that are perpetrated in their midst by ignorant midwives. The doctor also urged the necessity for supplementing the hospital work by opening a class where Parsee women may be educated in the duties required for sick nursing and lying-in rooms.

SUSPECTED POISONING CASES IN CALCUTTA.

DR. CHUNI LAL BOSE, M.B., F.C.S., one of the Chemical Examiners to the Government of Bengal, sends us the following report of five cases of suspected poisoning which occurred in Calcutta in January 1895:—

Case 1.—Soulamini Raur, Hindu female, of 120 Bow Bazar Street. *History as furnished by the Police:* Nothing known except that she had been drinking and was found dead in her room with her throat cut. *Opinion of the Police Surgeon who held post-mortem examination as to the cause of death:* Hemorrhage from the throat wound which was "homicidal." Viscera were forwarded to the Chemical Examiner to ascertain if she was first drugged and then murdered. *Result of chemical analysis of viscera and other substances:* Traces of alcohol detected; no other poison detected in the viscera. *Verdict of the Coroner's Jury:* Murder, but committed by whom, not known.

Case 2.—F. Webster, European male, 18 Ekbalpore Road. *History as furnished by the Police:* Lost his appointment and was unsuccessful in his efforts to get re-appointed. Was found dead in his room with a bottle of medicine in his pocket. *Opinion of the Police Surgeon who held post-mortem examination as to the cause of death:* Reserved. *Result of chemical analysis of viscera and other substances:* Chloral hydrate detected in the viscera. The bottle found with the deceased contained about 2 ounces of chloral hydrate. *Verdict of the Coroner's Jury:* Suicide by chloral hydrate.

Case 3.—Nayan Manjari Dasi, Hindu female, 365 Upper Chitpore Road. *History as furnished by the Police:* Had a quarrel with her husband who slapped her on the day of her death. Was found hanged in her room. Viscera forwarded to ascertain if she took any drug before resorting to the use of the rope. *Opinion of the Police Surgeon who held post-mortem examination as to the cause of death:* Hanging. *Result of chemical analysis of viscera and other substances:* No poison in the viscera. *Verdict of the Coroner's Jury:* Suicide by hanging.

Case 4.—Ram Lal Dasa, Hindu male, of Raja Nobokissen's Street. *History as furnished by the Police:* Had a quarrel with his kept woman. Was suffering from fever previous to his death. Body found in a decomposed condition in a room locked from inside. *Opinion of the Police Surgeon who held post-mortem examination as to the cause of death:* Reserved. *Result of chemical analysis of viscera and other substances:* Opium detected in the viscera. *Verdict of the Coroner's Jury:* Suicide by opium.

Case 5.—Kusum Raur, Hindu female, 56 Rutan Sirkar's Garden Street. *History as furnished by the Police:* Was suffering from some chronic disease, and often used to complain of being tired of her life. Was found unconscious in her room and taken by the Police to the Mayo Hospital, where she died.

Opinion of the Police Surgeon who held post-mortem examination into the cause of death: Opium poisoning. Result of chemical analysis of viscera and other substances: Viscera not sent to the Chemical Examiner as solid opium was detected in the stomach. Verdict of the Coroner's Jury: Suicide by opium.

OUR INDIAN JAILS AND PRISONERS.

INDIA numbers 37 central, 200 district, and 623 subordinate (or lock-up) jails, and the beginning of the year under report found 92,296 males and 3,000 female prisoners incarcerated in these jails. The admissions during the year were 430,836 males and 21,000 females; 430,918 males and 21,162 females having served out their sentences, the close of the year showed 92,214 male and 2,838 female prisoners still under sentence. Thus giving a total daily average of 94,964, of which the rate per 1,000 was 642 Hindus, 258 Mahomedans, 67 Buddhists and Jains, 13 Christians and 20 of other classes of convicts. The mortality per thousand was *high* in Coorg, being 75.56 and *lowest* in the North-West Provinces, where it was only 17.17. Over-crowded Bombay gives 25.44, Bengal 32.33, Burma 24.65, Madras 23.19, Punjab 26.60, Central Provinces 19.01, Assam 46.99 and Hyderabad Assigned Districts 28 per thousand; but when individual jails are taken, the figures are somewhat startling and lead to the conclusion that because the jail bird has been veiled enough to do what has brought him within the prison walls, he has forfeited his right to sanitary protection. Thus in three Burman jails the death-rate ranged from 111 to 131 *per mille*, while five Bengal jails give between 56 and 112. But energetic efforts are now being made with a view to reducing this mortality by improving the sanitary state of the food and surroundings of the prisoners.

CIVIL ASSISTANT SURGEONS AND HOSPITAL ASSISTANTS.

THE HON'BLE SURENDRO NATH BANERJEE, in his ably conducted paper, *The Bengalee*, in referring to the memorials recently submitted to Government says:—

"We are glad to find that the Indian Medical Association is making itself felt. Under the able leadership of Rai Lal Malhab Mukerjee Bahadur, it is manfully championing the cause of the Indian Assistant Surgeons. They are a useful body of public servants, but their position is not what it should be. The standard of qualifications is high—their remuneration small—their prospects are not what they have a right to expect. In the memorial which the Association have addressed to the Government, it is impossible to ignore the force of the arguments which are advanced. We await with interest the answer of the Government. In the meantime, if we are permitted to make a suggestion, we should advise the Association to continue the agitation which it has set on foot, and they are bound to succeed, because their prayer is so reasonable."

A WORD ABOUT YOUR BOYS.

MAKE home a pleasant place by treating your boy as though he were of some importance instead of a mere atom to be scolded. Furnish him with wholesome books and joining him in his reading, endeavour to draw out his opinions and thus help him to think for himself, but do not be too critical, lest he ceases to look upon you as his confidant. Actively interest yourself in all he does, and while teaching him orderliness and cleanliness be very careful of the courtesies, lest you dishearten him, for you cannot expect him to be thoughtful, tidy, respectful or kind unless you first set him the example. Never compare his shortcomings with the good behaviour, &c., of some neighbour's son, and above all do not keep him in ignorance of things that he ought to know; for it is not the plain truth, but the unwholesome way in which it is acquired that drives many a young man to perdition.

UNQUALIFIED ASSISTANTS.

THE General Medical Council of Great Britain has passed the following resolutions for the guidance of medical men who are under its jurisdiction:—

"A registered medical practitioner would render himself liable to the censure of the Medical Council in case of the employment of an unqualified assistant in the practice of medicine, surgery, or midwifery on behalf and for the benefit of such registered practitioner, either in complete substitution for his own services or under circumstances in which due personal supervision and control are not, or cannot be, exercised by the said registered practitioner.

"That the Council recon on its minutes, for the information of those whom it may concern, that charges of gross misconduct in the employment of unqualified practitioners in respect of the signing of medical certificates required for the purposes of any law or lawful contract are, and if brought before the Council, will be regarded by the Council as charges of infamous conduct under the Medical Act."

PHYSICAL EDUCATION IN OUR SCHOOLS.

The Bombay Government recently resolved not to make physical training in schools and colleges compulsory, as was suggested to the Government. The Indian Government decided against the suggestion, after careful consideration of the opinions of the Director of Public Instruction and of the educational officers of the Presidency, as there was sufficient evidence of the physical training in schools and colleges being voluntarily availed of. We would again press on the consideration of the different Governments, and of the heads of all our educational institutions the very great necessity for arranging for the periodical inspection and examination of pupils by medical men, so that the serious danger of pupils being put to severe physical strains, or to exercises ill-suited to their physique and constitutions, may be guarded against.

THE MILITARY PUPIL CLASS IN CALCUTTA.

AT present there are 88 military medical pupils in the Calcutta Medical College. Thirty of these will leave college in a month as qualified Assistant Surgeons, and 25 more at the end of twelve months. The estimated allowances for this class should keep the total number of students at 100. If this were done, the college authorities could easily advertise for 48 vacancies to be filled up in another few weeks. We would be glad to see Botany, Hygiene and Practical Chemistry made compulsory subjects of the curriculum for this class instead of their being optional as they are now. It would also be a definite gain to Government if the Entrance Examination of our Indian universities were made the educational standard for admission to this class and if the course of study was prolonged to five years.

THE DISCOVERY OF ANÆSTHESIA.

A TABLET of bronze, to the memory of DR. HORACE WELLS, of Hartford, Conn., was unveiled on 11th December 1894, in commemoration of the fiftieth anniversary of the discovery of nitrous oxide as an anæsthetic. On 11th December 1844, DR. JOHN M. RIGGS, at WELLS's request, administered nitrous oxide to him and extracted a tooth under the influence of the gas without causing him any pain. The tablet bears a medallion portrait of HORACE WELLS, with the following inscription: "To the memory of HORACE WELLS, the dentist, who upon this spot, 11th December 1844, submitted to a surgical operation, discovered, demonstrated and proclaimed the blessings of anæsthesia."

A PRINCELY DONATION TO THE I. M. A.

HIS HIGHNESS SIR BHAGVAT SINGH, M.A., M.R.C.P., LL.D., K.C.I.E., THAKUR SARKAR OF GONDAL, Vice-President of the Indian Medical Association, has very kindly sent a donation of Rs. 500 for the Library of the Association. SIR BHAGVAT SINGH's gift is most thankfully appreciated by every member of the Indian Medical Association.

"A SILENT TONGUE SHOWETH A WISE HEAD."

THE recent experience of a Leeds doctor confirms the dictum that "silence is golden," for having on a dentist's enquiries given certain information regarding the health of a young lady whom the dentist was attending for her teeth, her young man inveigled the doctor into the young lady's house, and after forcibly obtaining the doctor's apology in writing, took further satisfaction in thrashing him. The doctor sued his assailant but the defence set up of provocation, was not admitted, and a fine of three pounds and costs, was imposed on the young lady's gallant protector. There is more than one reason for observing professional secrecy and reticence in respect to our patient's ailments.

THE SALE OF POISONS.

COMMENTING on the papers read on this subject at the Indian Medical Congress, the *Times of India* urges the necessity for insisting on measures restraining the procuring and sale of poisons, even though it may not be possible to check or censure Nature for so prolifically furnishing every hedge, field or garden in India with poisonous plants available to the homicide or suicide. He complains that the Bombay Poisons Act is far too insufficient, and while expressing surprise that Bengal is absolutely devoid of any law restricting the sale of deadly drugs, points out that, comparatively speaking, the suicides by poison were sixteen times as many for Calcutta alone, than for England and Wales combined.

TRACKING TYPHOID.

IN consequence of an outbreak of virulent typhoid in the 16th Queens' Lancets, MR. HANKIN made certain investigations which ran the typhoid bacilli to earth on the banks of a *nullah* where human dejecta, containing the bacillus, was pretty freely distributed. These bacilli, MR. HANKIN thinks were carried to the men's quarters either by the wind or by the milk and butter obtained from cows that habitually drank this *nullah-water* in preference to the clean water provided for them.

GOVERNMENT AS DISPENSER OF QUININE.

FOLLOWING up the example of Bengal, and the enormous success obtained in distributing genuine quinine cheaply to the poorer classes, the Bombay Government has, with the suggestions of Surgeon-General PINKERTON, resolved that the prisoners in Yerawda Central Jail shall put up Government quinine in five-grain packets, which will be sold by all the civil hospitals, dispensaries and post offices within the presidency at one pie (*i.e.*, three pices) per packet to the general public.

AN INDIAN DOCTOR FOR THE AMIR OF KABUL.

THE AMIR has asked the Indian Government for the services of a reliable native medical officer for Kabul. Khan Bahadur DR. RAHIM KHAN, Honorary Surgeon to the Viceroy, and a Professor of the Medical College, Lahore, of whom good reports have evidently reached Afghanistan, has, it is stated, been specially named by the AMIR; but it is doubtful whether DR. RAHIM KHAN will accept the AMIR's offer of appointment as his private physician, however tempting it may be. The Punjab Government in that case will probably send DR. AMIR SHAH, also of Lahore.

DR. FATEH CHAND

OUR worthy friend, DR. FATEH CHAND, of Lahore, still continues in the service of Government. We were led to believe he was retiring from the service and entering independent practice; but DR. FATEH CHAND writes to us to say he is unshaken of severing his connection with Government. There can be no question that DR. FATEH CHAND possesses rare abilities, and these can profitably be utilised by the State. We would therefore be glad to see him obtain a good appointment.

NEW MEMBERS OF THE INDIAN MEDICAL ASSOCIATION.

We have pleasure in publishing the names of the following gentlemen who have joined the Association since our last issue:

Jogendronath Ghosh, L.M.S., Teacher of Midwifery, Campbell Medical School, 46, Nebutolla Lane, Calcutta.

A. X. Dias, Asst. Surgeon, I. M. S., Station Hospital, Deolali.

C. M. D'Souza, Asst. Surgeon, I. M. S., Station Hospital, Deolali.

H. A. Lafond, Asst. Surgeon, I. M. S., Station Hospital, Deolali.

Geo. R. Chamarette, Asst. Surgeon, I. M. S., Station Hospital, Deolali.

George W. Beaumont, Asst. Surgeon, I. M. S., in medical charge G. I. P. Ry. Disp. and Civil Hospital, Bhussawal.

V. Chengalroya Moddellar, C.M.S., Hospital Assistant, Station Hospital, Bellary.

Medical men and women in all parts of India and Burma who desire to take a share in aiding the advancement of the Indian Medical Association are cordially requested to write to the Editor of the *Indian Medical Record*, and he will gladly send them blank membership forms and prospectuses. We are glad to find many willing volunteers.

SHORT ITEMS.

We have much pleasure in announcing the return of DR. D. N. CHATTERJEE to Calcutta, after five years' residence in Great Britain. He joined the University of Edinburgh, and after a successful career obtained the degrees of Bachelor of Medicine and Master of Surgery. DR. CHATTERJEE intends to practise in Calcutta, at 18 Bendon Street. We wish him every success.

The *Nursing Record* of London, which is rising rapidly in power, says:—"Our views remain that midwives, pure and simple, are an anachronism, that midwifery adopted as a speciality by thoroughly-trained nurses is a useful branch of their work, but that such workers must be registered as "Obstetric Nurses," not as practitioners of midwifery."

The Madras Government, at the instance of the Dewan of Cochin, has applied to the Secretary of State for the services of a suitable man to take up the appointment of Medical Officer to the Cochin Durbar, which will fall vacant in July next.

Newspapers in India have been roused to protest against some of their craft being subsidised by Government. They are memorialising Parliament against such flagrant injustice and corruption. Will the *Indian Medical Gazette* be included among the subsidised papers?

In the Punjab University the number of lectures required in each course of the following subjects is reduced from 100 to 70: Descriptive and Surgical Anatomy, Chemistry, General Anatomy and Physiology, Medicine and Surgery. This is a mistake.

The First Arts or Intermediate Examination in Arts, is now the preliminary test for candidates for medical diplomas in the Punjab University. This brings it in line with Calcutta, Bombay and Madras.

Lady Paget, the wife of Sir James Paget, Bart., M.D., died on the 7th January 1895, aged 60 years.

The preliminary educational tests for medical diplomas from the British Corporations and most of the British Universities are much inferior to the preliminary standard required for the diploma of an Indian university.

The Secretary of State having declined to grant an extension, it is now definitely settled that Dr. Bradshaw, P. M. O., Her Majesty's Forces in India, shortly retires from the service, and that Surgeon-Colonel Gore from Mhow succeeds him.

Here's another guess! The *British Medical Journal* says:—We understand that it is probable that Surgeon Major-General T. Walsh, P. M. O. Madras, will be the successor of Surgeon Major-General Bradshaw as P. M. O. of India.

Messrs. Smith, Stanistreet and Co., of Calcutta have notified the profession that they have received a stock of Behring's antitoxin for the cure of diphtheria. Also that they have an excellent shew of modern surgical instruments.

We are glad to notice that Dr. Kader Nath Sen, L.M.S., a medical practitioner of 20 years' standing, has removed to Calcutta. Dr. Sen enjoyed an extensive practice in Hooghly and Chinsurah.

Sir Richard James was the first Eurasian baronet. His mother was an Indian lady and his father Sir William James, Bart., was Chairman of the East India Company, and died 18th December 1788.

The Lady Reay Medical Scholarship, tenable for one year, has been awarded to Bachubai Mancher Datur, of the Empress High School for girls.

Assistant Surgeon William Forrester, I. M. S. (Bengal), has successfully passed the examinations and has obtained the diplomas of M. R. C. S. Eng. and L. R. C. P. London.

The Eurasian and Anglo-Indian Association of Madras has 1,272 members. What an object lesson for Calcutta and Bombay!

A testimonial to Sir Joseph Fayrer, M.D., is suggested. It will take the form of an oil painting of this famous old Indian hero. The limit of subscription for India is Rs. 10. Surgeon-Colonel Lane Notter, A. M. S., Netley, is treasurer.

Brigade Surgeon J. C. Whishaw, I. M. S., for many years Civil Surgeon of Lucknow, died at Mentone on the 20th January 1895 at the age of 62.

* There were 33, 2, 1 and 16 deaths from *Beri-beri*; and 1, 26, 177 and 0 deaths from *Kala-azar* in these four districts, respectively.

OUR LONDON LETTER.

(From our own Correspondent.)

FOLLOWING the even tenor of my correspondence, I may indicate the fact that foggy weather with snow is falling upon the "great metropolis." The thermometer during several nights has fallen below 32°F. Typhoid and diphtheria are still common in our midst. Our great hospitals are indeed busy. I visited St. Bartholomews yesterday and there was scarcely a bed to be had. The current medical literature is fairly teeming with reports of cases of that plague *diphtheria, treated by the new antitoxin serum*. BEHRING'S, ARONSON'S and ROUX'S being used.

The *British Medical Journal* publishes an admirable table of the cases treated by the several forms of antitoxin in vogue in France, Germany, &c., also successes obtained at Netley, St. Bartholomews and St. Mary's Hospitals.

Some of our leading physicians and surgeons are inviting subscriptions to raise a monument to late DR. BEAVER NAKE RAKE of Trinidad, who did such prominent work in connection with the Royal Commission of enquiry into Leprosy in India. Among the curiosities agitating the credulous and superstitious is the belief of miraculous cures at St. Winifred's Well. After this, and with pilgrims of Lourdes can we in sooth say that we have rent the veil from the alchemic science of the dark ages, for the plebs of England are still, we must admit, highly strung as to their imaginative faculties. The laity especially in Wales still believe in certain curious and wonder-working cures.

The Edinburgh University Court has at length determined to recognise the lecturers of the Edinburgh School of Medicine for Women and of the Edinburgh Medical College for Women as "lecturers especially appointed by the University." M. JEX BLAKE, M.D., is the leading spirit, as Dean of the School of Medicine in throwing open this splendid degree to her sex.

DR. WALTER DIXON, R.N., has passed away. He had a meritorious and eventful career. Becoming M.D. Edinburgh 1841, he served on the West Coast of Africa, in the Baltic, during the Indian mutiny, during the Russian war holding an important commission. He was Senior Medical Officer in the naval operations against China, 1859-60. Among his contributions to medical literature was the Medical History of H. M. S. Chesapeake in India and Arabia; this gained for him the Blaine gold medal.

London will soon be able to boast of a new medical society, which will be styled the New Clinical Society, to be organised by the staff of the North-West London Hospital. This may prove opportune, as the practitioners of North London have determined to turn their backs upon the consultant staff of the Great Northern Hospital since the opening of *pay wards* there. The immediate consequence of this determination will certainly mean the resignation of ~~members~~ of the members of the North London Medical-Chirurgical Society.

A new general order to effect re-organisation of the I. M. S. threatens to bring about some changes in the Indian service of a startling character, is practically settled, and the order will doubtless be shortly published and will make alterations among military

men too. There is a vacancy among the staff of the Westminster Hospital. Their urbane senior physician, OCTAVIUS STURGES, M.D., F.R.C.P. London, while crossing Cavendish Square was knocked down by a cab and received injuries which terminated fatally. The reason of this accident happening, was owing to slight deafness from which the deceased suffered, precluded his hearing the approaching vehicle, the wheels of it being protected by India rubber tyres. The kindly face well liked by all has left us, and the students in the wards no longer hear his genial tones. DR. STURGES was born in London 1833, went to Addiscombe as a cadet in East India Company's service, thence he passed out to India as a Lieutenant, Bombay Artillery, after 5 years returned to London and entered as a student at St. George's Hospital, becoming Medical Registrar 1863, and also entered at Emmanuel College, Cambridge, B. A. and M. B. 1862, M. R. C. P. 1863. In 1867 M. D. Cantab. 1870. F. R. C. P. London. Assistant Physician, Westminster Hospital 1868. He became successively Lecturer in Forensic Medicine till 1871, when he lectured on Materia Medica. In 1874 he succeeded DR. ANSTREY in the chair of medicine, which he resigned only last year; elected physician 1875; till his death, physician to Great Ormond Hospital for sick Children. His literary work included "Chorea" and that on "Pneumonia." These are vivid pictures of the diseases most clear and striking in their style. His disposition was peaceable, and his humour was most kindly. He was a delightful companion, widely read and discriminative.

Ipecacuanha tabloids keratin coated have just been manufactured and can be obtained from Messrs. Burroughs Wellcome and Co., London. *These elegantly made and coated tabloids are therapeutically and pharmaceutically a great advance upon the Pulvis Ipecacuanha Co. of the B. P., which was regarded at one time almost as a specific in endemic and epidemic dysentery.* The use of ipecacuanha tabloids in the treatment of dysentery, with the additional use of enemata of haseline in warm water solution is now a recognised and valuable method.

A meeting was held at the Holborn Restaurant for the purpose of initiating a society composed of surgeons engaged in *orthopaedic work*, MR. NOBLE SMITH being in the chair. This body is to be styled "The British Orthopaedic Society," established to advance the study of orthopaedics.

There have been several prosecutions under the Apothecaries' Act. An action has been brought by a groom against DR. T. O'BRIEN to the extent of £1,000; the plaintiff alleging that he had sustained loss and injuries due to negligence of his medical attendant. The jury found a verdict for the plaintiff and allowed £175 damages.

The President, R. C. S. I., disapproves of the policy of his associates on the General Medical Council in agreeing to an additional year of study and raising the standard of examination which he earnestly condemns. This Council has been again in session for 9 days under the presidency of SIR RICHARD QUAIN, Bart. This is their 57th session, the object of which is to encourage reforms and abolish abuses, in other words, purge the chaff from the profession. The first subject attacked was the revision of the final examination of Glasgow University, which were deemed

satisfactory, when explained and this opinion was carried on the motion of Sir DYCE DUCKWORTH.

The examinations of the Aberdeen University were deemed sufficient. Reports were handed in on examinations in public health in the Universities of Edinburgh, Cambridge and Durham. The Certificates of midwives were discussed in camera. Thirty-four penal cases were gone through. The five years' curriculum led to a warm debate as to changes in schedule, &c.

A new pharmacopœia came under consideration. The Council also complained of the *Lancet* publishing a report prematurely, and some members of the Council were for censuring the proceeding of that "energetic reformer," which perhaps rightly seems to think that such matters should be treated of "*coram publico medico*." Some resolutions were then passed as to the regular mode of procedure to have a name, when once erased from the Register, replaced thereon.

A lecture was given by Dr. SIMS WOODHEAD under the auspices of the British Institute of Public Health on "*The diagnosis and antitoxic serum treatment of diphtheria*." There has been a new society, formed in London consisting of members R. C. S. England. Drs. RUSSELL, REYNOLDS, HERMAN WEBER, POWELL, R. DOUGLAS, and CHEDIAK have been elected consulting physicians of the Royal National Hospital for consumption.

The death is announced of Deputy Surgeon-General E. H. ROBERTS, who retired in 1888. He had served in the Crimea, being present at the siege and fall of Sebastopol and throughout the Indian Mutiny (1857-58) he was on duty at the siege and capture of Lucknow.

The London Building Act will shortly be debated in all its aspects at a meeting of the Sanitary Institute. War is being waged strongly by the Medical Practitioners' Association on the introduction of *pay wards* at the Great Northern Hospital.

Dr. FRANCIS BISSSETT HAWKINS, who was the oldest graduate of Oxford University, has died at the venerable age of 98 years. Fifty years ago, he was perhaps one of the most distinguished graduates of that time, of his honored *alma mater*, and one of the most prominent Fellows of the R. C. P., London. *Sic transit gloria mundi!*

Mr. T. HOLMES, F.R.C.S., has been elected Treasurer of St. George's Hospitals, being a consultive surgeon of that institution already. Dr. DEHAVILLAND HALL has, after devoting 19 years to the out-patients, been appointed physician, *vice* Dr. O. Sturges, lately deceased.

In connection with the *Westminster Hospital* it has been determined to raise a memorial to Dr. STARGES their deceased senior physician. Dr. HUGHLINGS JACKSON has retired from the active staff of the London Hospital, and the students desire to commemorate the retirement of such a distinguished neurologist. PROFESSOR W. R. SMITH, M.D., F.R.S.E., D.Sc. barrister-at-law, Professor and Forensic Director of the Laboratories of State Medicine, Medical Officer of the Schoolboard for London and Manager of Metropolitan Asylums Board was presented with a service of plate by the Lord Mayor, acting for the Fellows and Members and Associates of the British Institute of Public Health.

The latest development of "*the fever theory*" emanates from Bucharest from the mouth of PROFESSOR DEMOTHENIS, who advises gravely the use of a metal purse capable of ready sterilisation, by those who receive fees at the bedside, and the routine washing of the hands before leaving the patient's room, but a medical contemporary stigmatises this "hyperantisepticism" as a sort of transcendentalism. *Drug adulterations* of the most grandlun character is a trade extensively carried on, aye and patronised too. Twelve prosecutions were recorded by the Pharmaceutical Society. *Seropathy* still marches progressively onwards. Weekly notices occur in the journals, of diphtheria cases treated successfully by anti-diphtheritic serum. The patients of the different London hospitals, especially the children, have been having a joyous time. Special food was provided. Spirits, wines and tobacco being distributed to not a few. The medical and nursing staff being energetic and successful in decorating the wards and providing heaps of toys for the sick children. Their friends, too, had special permission to visit them in the course of the afternoon.

The report of the Chief Commissioner of Police shews that the rapid increase of London during 1894 was due to the following items; no less than 12,633 new houses were built and 100 new streets completed. He also shews the number killed in the streets during the year amounted to 1,601 persons, and 6,336 injured. Startling intelligence has just reached me that, during the great gale which swept over England on the night of December 23rd last, the children's ward in Blackburn Infirmary collapsed, burying 7 of its inmates in the ruins. All the children escaped with their lives, but some were badly injured.

At a meeting of the Hunterian Society, Dr. ARTHUR DAVIES raised a discussion on *Skin Diseases treated by thyroid feeding*. He said that the tabloids he used equalled $\frac{1}{2}$ of a gland, and that very small doses produced appreciable symptoms in myxodematous or neurotic patients. He further demonstrated by lantern slides, various cases of *psoriasis*, &c., before and after the treatment by thyroid gland tissue. Dr. P. S. ABRAHAM exhibited his third case of *lupus vulgaris* treated by thyroid tabloids. He had tried the remedy in 2 cases of *leprosy* with some benefit. In one case the disease became stationary for a period of 12 months. Dr. BEAVER RAKE had tried tabloids in 5 cases at the Leper Asylum at Trinidad, but his supply of these agents was inadequate, and the disease was of years standing—result negative. He mentioned the case of a female subject to *alopecia areata*, in which administration of thyroid gland had caused a general sprouting of hair over scalp, eyebrows and elsewhere.

Dr. BRUNNER of Zurich has contributed an interesting monograph on the history of military surgery and hygiene among the ancient Romans. Dr. KLEIN, F.R.S., at a meeting of the Clinical Society, took as the subject of a discourse "The relations of bacteria to their toxins." Drs. WASHBOURN and GODDALL have brought forward details of eighty cases of diphtheria, proved by bacteriological diagnosis, treated with good results by "anti-diphtheritic serum" subcutaneously injected.

Accident sometimes happen through playing with even toy firearms. A young lady, residing in the suburb of Clapham, met her death through discharging at herself a toy

pistol which chanced to be loaded. The attention of our legislators should be called to the dangers of keeping loaded weapons lying about the premises. All such lethal instruments should be kept under lock and key, and children never, under any circumstances, allowed access to them.

Rabies has broken out in Leeds, and the parochial authorities have made the magnificent offer to policemen, who are to receive 3d. per head of each suspicious dog captured, risking life, so to speak, for about half a pint of ale! Generous, is it not? It is to be hoped, under the circumstances, that should a constable spy a suspicious looking member of the canine family, he will dart away in the opposite direction.

DR. MASON has published his report on the 1893 cholera outbreak in Hull. He details 17 cases with 12 deaths (a mortality rate of 70 per cent). He seems to regard it as a recrudescence of the 1892 attack. Cases of over-work and sweating in laundries are reported. Death provoking the attention of the authorities to the subject as usual.

DR. HERMANN WEBER has handed over to the R. C. P. London a sum of money to provide a WEBER medal and prize for research on the subject of tuberculosis.

A dentist has successfully sued a lady patient for the sum of £23 for the supply of dentures and visits, claiming solely on the ground of professional skill.

The *Britannia* takes out the undermentioned surgeons for service in India:—Surgeon Lieutenant-Colonel DREW, Surgeon-Captain MORGAN and Surgeon-Lieutenant MACDERMOTT. Surgeon-Captain A. R. ALDRIDGE has reported himself at Netley for duty. Surgeon-Lieutenant MOORE, Netley, is under orders for India shortly.

Dermatology has reached in our day the standard of a special branch. It is practised now by some of our most eminent physicians and surgeons. Therefore to offer a few words on one of the most active dermatological remedies will not be deemed out of place in this fortnightly correspondence. The drug we present for remark is *Ichthyol* (this is a sulpho-ichthyolate of ammonium) and like all sulphur derivatives is lethal to various micro-organisms.

MALCOLM MORRIS, in his work on "Diseases of the Skin" states that this drug is perhaps more effective than any other, in the reduction of hyperæmia. It destroys the vitality of streptococci in erysipelas. The *Practitioner* confirms its utility in pruritus, erysipelas and dermatitis.

OCHSEN, *Medical Times*, March 4th 1893, advises its use in a common complaint—"sore nipples"—JUEL RENOY and HALLOPEAN advises it as a paint in erysipelas. SCHROIMMER indicates it in all skin complaints with cutaneous hyperæmia. It is feasible that a 10 per cent. solution should be painted over small-pox pustules. DR. SHEWALL THOMAS gives additional confirmation as to its immense value in erysipelas. FREUND and others give a high estimate of its therapeutic utility in inflammatory affections of the female genitals, stating that it is an anodyne and absorbent. Metritis of long standing can be cured, says DR. E. TURNER, by giving 3 tablets of ichthyol (B. W. & Co.) per diem. The *British Medical Journal* reports cases of exfoliative dermatitis, psoriasis, ichthyosis, acne vulgaris and voraces in which ichthyol proved most serviceable. DR. CHATELAIN used ichthyol with good effect in leprosy. Neuralgic pains with inflammation may be relieved

by subcutaneous injections of this drug, (*Edinburgh Medical Journal*). In *The Lancet* MR. J. K. TOMORY relates the cure of a female patient who had suffered from eczema for 3 years, was cured in about a month by the outward application of ichthyol. The eruption affected the back of the neck and scalp. This remedy was introduced by DR. G. P. UNNA (Hamburg) who first brought it under the notice of the profession in 1883 as a topical application in skin diseases with capillary congestion. Later on it was used extensively in gonorrhœa and uterine complaints. DR. CRANSTOWN CHARLES corroborated fully DR. UNNA'S views, and remarked that it acted by abstracting oxygen from the tissues. Its dose internally varies from 2½ to 10 grains, preferably given in tablets.

We have collected notes of about 1,850 cases of diphtheria treated with "Anti-diphtheritic Serum" injections. The mortality of these cases varies from 5 per cent to that of 24.33 in ROUX'S (448) cases. Some German observers have a mortality of 28 per cent in England. In DR. WASHBURN'S series of 72 cases of diphtheria (diagnosed bacteriologically) there was a mortality of 19.4 per cent.

Current Medical Literature.

MEDICINE.

Malarial Parasites in America.

OSLEN distinguishes three varieties of the malarial parasite: (1) the tertian, (2) the quartan, and (3) the æstivo-autumnal. The first requiring 48 hours' complete development is associated with relatively regular tertian paroxysms, lasting 10 to 12 hours and exhibiting the three classical stages of chill, fever and sweating; but infection by two groups of tertian organisms may give rise to quotidian paroxysms and by multiple groups to more irregular subcontinuous fever. The second, though rather rare, develops in about 72 hours, being associated with a fever showing regular quartan paroxysms, and infection with 2 groups produces fever on two days with intermission on the third, but infection by the groups of the parasite produce daily paroxysms. The third developing in from 24 to 48 hours or more has the spleen bone marrow and internal organs for its main seat of infection, and is associated with fevers that may be quotidian tertian, intermittent or continuous, with irregular remissions and irregular variations of temperature; but the individual paroxysms last about 24 hours. Quinine, which exerts its influence most strongly when the parasite is undergoing segmentation just prior to entering into new red corpuscles. Its action is much more rapid and certain with the tertian and quartan than the æstivo-autumnal infection; but to be of any use it must be given just before the beginning of a spasm.

Dietetic treatment of Diabetes Mellitus.

WILLIAMSON, who deprecates gluten on the score of expense, ureliability, and intolerance, advocates strongly in favor of HONDHAUSEN'S *aleuronant*, which is a cheap form of vegetable albumen, prepared from wheat and capable of substituting flour for soups, sauces, &c., as also of being baked as bread by the addition to it of an equal bulk of wheat flour. PAVY recommends almond cakes as a substitute for bread. The sugar being dissolved out and a mass free from carbohydrate obtained by washing the almond meal with boiling acidified water; but this substance is not only expensive, but it is also difficult of digestion by virtue of the oil and fat it contains, *Sundby Nielsen*, which is the soluble gelatinous substance contained in Icelandic moss (*Odieria*) after deprivation of its bitter principle—a capital food but unfortunately one that only wealthy patients can afford.

The Etiology of Paludism.

SINCE the discovery by DR. LAVERAN of hæmatozoal parasites in the blood of malarial fever patients, numerous observers have given testimony to the existence of these parasites (*Plasmodium malarium*) in every case of paludal fever, but though these parasites assume such a number of forms as to lend to the impression of belonging to several distinct species and prompt some observers into trying to classify them, LAVERAN has proved to the hilt that while the same form of parasite may be observed in intermittent and in regular fevers, the same fever often presents several distinct forms (not species) of hæmatozoa in the blood, and the fact that in every part of the world malarial fevers readily yield to quinine, coupled with the marked effect of antiperiodic treatment on the blood, tend to confirm the opinion that instead of belonging to a plurality of species the different forms of *plasmodium malarium* mark the stages of the development of the same parasite under different climatic influences and morbid conditions of the blood.

Ricketts as an Infectious Disease.

PAUROT's syphilitic theory having fallen to the ground, because malnutrition rather leads to athrepsia and marasmus than to rickets, which can scarcely be due to defective assimilation of calcium phosphate under digestive disturbances, and as no proof is forthcoming to the theory that attributes rickets to the dissolution of the lime salts of the bones by excessive secretion of lactic acid in the stomach as the result of diarrhoea and digestive disorders, CHAUMIER propounded the theory that rickets is "a specific disease produced by an unknown microbe." The epidemic at Indre-et-Loire and the observations of BAGINSKY, BONADEL, CHAUMIER and HENOCCH lead to the conclusion that rickets is also a contagious disease. FEDER thinks that the microbial theory is just as good as any other, since nothing is positively known of the pathogeny of rickets, and PUECH asks whether it is safe to conclude that rickets is an "infectious, parasitic or a specific disease, the microbe of which produces only rickets."

A Peculiar Case of so-called Neuritis.

A FEMALE æt. 21, who four years previously had severe darting pains in the hands and forearms, subsiding into wasting and loss of power, consulted DR. HAROLD N. MOYER for the following symptoms:—Fibillary tremors; intense but symmetrical atrophy of hypothenar and thenar eminences, interosseous muscles and both forearms below the elbow sensibility to all forms of stimulation was diminished or lost as high as the middle third of left arm, and extending up to the shoulder and a portion of the anterior thorax on right side; exaggerated knee-jerk and ankle clonus of both sides; very irregular faradaic and electrical responses; nystagmus; vision good and fundi unaltered. DR. MOYER diagnosed this case as an anomalous one of peripheral neuritis; but the *Lancet* thinks it was a central disease of the cord involving both the anterior cornua and the white matter, and producing descending degeneration in the pyramidal tracts.

Typhoid Fever and Oyster-eating.

SEVERAL of the Middletown Co. University students having been seized by typhoid fever after one of the initiation suppers, DR. H. W. COX made a patient enquiry which traced the disease home to some oysters fished from the deep water of Long Island Sound and then deposited to "fatten" at the mouth of a fresh-water stream, close by a private sewer belonging to a house, wherein a lady and her daughter had, a few days previously, been laid up with typhoid fever, the germs of which had passed with the dejecta into the stream where these oysters were fattening.

Pernicious Anæmia at 21.

As it is not often that a case of pernicious anæmia is seen during the first 25 years of life, DR. W. E. GOWANS mentions a case where a young man of 21 was brought to him with numerous flame-shaped hæmorrhages in his retina, scopic, short-winded, cadaveric countenance and very pale gums and conjunctivæ, while the percentage of red-blood corpuscles was barely 25; the hæmoglobin had sunk to a trifle over 30 per cent., and other symptoms of bad chlorosis. In spite of careful treatment, he steadily failed, and his temperature rose for a few days. Pyrexia returned on the 30th day, when a large hæmorrhage occurred in the right eye and vomiting setting in, the patient died two days later.

SURGERY.

Stomach-recting.

THIS operation has been performed by DR. BRANDT for dilatation of the stomach. It is well known that the stomach becomes enlarged in cases of pyloric stenosis due to new growth, cicatricial contraction, or bands of adhesions. The rational treatment of this stomach trouble is the removal of the cause. This is accomplished by pylorus resection and excision of pyloric cicatrices, which have been so successfully done during the past few years. It sometimes happens, however, that after opening the abdomen no such cause is found for the dilatation. If the wound is closed, the laparotomy has been nothing more than an explorative operation, and the patient continues to suffer from the disease; the case being then regarded as a medical one, and a subject for medical treatment. It has occurred to BRANDT to treat these idiopathic cases by diminishing the size of the stomach by folding in its wall and suturing it through the serosa and muscularis. The patient upon whom he operated was a woman, twenty-six years of age. The gastric sound could be introduced till it struck the pubes and left POUPART'S ligament. Palpation revealed no tumor of the pyloric or other region, nor even an abnormal resistance. The patient was poorly nourished and greatly reduced in strength. She was treated medically by faradisation and lavage of the stomach, with little improvement. After this treatment had been carried on for two months, BRANDT made an opening into the abdomen parallel with the left costal arch, and explored the stomach and other abdominal contents. Pylorus was especially examined, and nothing found. The organ was found enormously enlarged. He then proceeded to fold in the anterior wall and suture it by two rows of transverse sutures. The same was done on the posterior wall through holes torn through the great omentum. More than two hundred sutures were applied. The patient made an excellent recovery, without any disturbance of digestion, and was able to leave her bed on the tenth day. BRANDT has published this case as preliminary to a more exhaustive communication upon the subject. The same operation has been described under the head of "gastrople" in the same periodical.—*Annals of Surgery*.

Contagious Eye Diseases and Preventible Blindness: their Etiology and Prevention.

COMMENTING on the statement of the United States Census bureau, that of a total population of 62,624,350 souls 50,568 were blind, DR. J. MONROE RAY thinks that a good deal of this blindness could have been prevented by making general the New York State law that heavily punishes the midwife or nurse who neglects to report redness of eye or both eyes that appears in any infant within two weeks of its birth. In his opinion contagion and highly acrimonious results

are threatened in every case where inflamed conjunctiva are accompanied by the formation of a secretion. Under this category he brings ophthalmia neonatorum, trachoma or granular lids and gonorrhoeal ophthalmia; but he particularly emphasises ophthalmia neonatorum, which he thinks can be readily prevented by (a) controlling vaginal discharges during pregnancy, (b) thoroughly cleansing the vagina before delivery, and (c) by the moment delivery is over clean the child's eyes with a fluid that will either remove the injurious material or destroy its action. His method of dealing with the last set was to first wash the new born babe in the usual way and then after cleaning the eyelids with a pledget of cotton and clean water to allow to drop *one* drop of 2 per cent nitrate of silver solution. No ill results followed, but there was a great reduction in the percentage of blind persons.

The advantage of internal Urethrotomy over Forcible Dilatation.

CANTALUPO advocates internal urethrotomy in hard strictures where a dilator cannot be introduced, or, if introduced, cannot be opened (in which case he uses MAISONNEUVE'S urethrotome). The wound in internal urethrotomy is much less extensive than in forcible dilatation, and the dilatability of the stricture is much greater after urethrotomy than after division. The chief dangers are:—(1) Hæmorrhage; this may be avoided by using small-bladed instruments—for example, BOTTINI'S. (2) Extravasation of urine; best avoided by retaining a catheter of less calibre than the divided stricture, and using some drainage tube as a siphon. (3) Pyæmia may be excluded by antiseptic measures. (4) Fever, generally due to local retention of pus. CANTALUPO finds a fresh indication for internal urethrotomy in cases of chronic gleet with stricture, where after dilating the stricture up to a certain point, it still cannot be dilated up to the calibre of the sound part of the urethra.

Successful Splenectomy.

As a consequence of influenza and intense mental worry over monetary troubles, a female had a paralytic stroke from which she recovered, but the spleen beginning to enlarge and cause her a great deal of misery, she was admitted into the Sunderland Infirmary, where DR. JAMES MURPHY operated on her, removing a spleen 8.75 inches long, 9.13 inches superior and 10 inches lower circumference and weighing 1.5 lb. It was firmly adherent to the omentum and to two or three portions of the transverse colon. The adhesions being rapidly broken down and the pedicle secured by silk ligatures the spleen was extirpated and the abdominal wound closed. The hæmorrhage was excessive, but the woman rallied, and though convalescence was a little dilatory she was in 48 days after operation discharged from hospital quite free from pain. She has since put on flesh and appears to not suffer any inconvenience from the extirpation of her spleen.

Lactic Acid in Corneal Ulcers.

To prove MOSETH VON MOOREHOFF'S contention that lactic acid acted on diseased tissues but left healthy parts unaffected, DOLEZHOFF touched corneal ulcers of various stages and sizes with a thin piece of wood dipped in a fifty per cent solution of lactic acid. He was so well satisfied with the results obtained that he tried it in chronic trachomatous ulcers complicated with photophobia and dilated vessels of the eye. A single application of the lactic acid sufficed to arrest further progress of the ulcer by forming an eschar which, falling off in 3 or 4 days, left healthy cornea underneath. In those cases where the healthy portions of the cornea were accidentally touched the epithelium only was damaged and the spot completely healed by the following day.

Sarcoma of the Testis stimulating Hæmatocele.

THE tendency to hæmorrhage in the softer forms of malignant growth often render extremely difficult, even by exploratory puncture, a correct differential diagnosis of hæmatocele and malignant growth of the testicle. A man aged 38 came to DR. C. A. MORTON with a rapidly increasing swelling exhibiting the symptoms of hæmatocele which the exploratory puncture appeared to confirm; but on cutting open the swelling it was found to consist of very soft friable sarcoma enclosed within a greatly thickened tunica albuginea and in the centre of this mass was a cavity containing decolorised blood-clot, a portion of which must have escaped through the exploring cannula and given rise to the collection of brown fluid like hæmatocele fluid.

—O—

OBSTETRICS AND GYNÆCOLOGY.

Vaginal Hysterectomy.

AFTER rendering her vagina and genitals aseptic and placing the patient in the lithotomy position with her buttocks on a hard pillow and the perineum and posterior vaginal wall drawn down by a SIMON'S speculum, DR. A. J. MCCOSH curescutes or scrapes the cauliflower growths off the cervix, scrubs the ulcerated surface with a 1 per mille bichloride solution and applies the Paquelin cautery. Dragging the uterus downwards with a vulsellum he dissects the cervix away from the bladder and anterior vaginal wall—the incision being 0.5 inch away from the edge of the neoplasm—and carries the dissection laterally as far as the broad ligaments and up to but without wounding the peritoneum. Then separating the posterior vaginal wall and controlling bleeding by a running catgut suture, close to the vaginal edge, he makes a free incision through the peritoneum into DOUGLAS'S pouch, ligates the lower ends of the broad ligaments, which he severs from the uterus and after similarly ligating and cutting away the next portion of the ligaments he freely opens the peritoneal cavity over the anterior aspect of the fundus and removes the uterus bodily. Bleeding points attended to the tubes, ovaries and adnexa are carefully examined and, if they are healthy and have no downward tendency, they are not disturbed; but if they appear infiltrated with inflammatory or other material or fall into the opening, they are excised together with as much as possible of the ligaments. The peritoneum having been sutured to the cut edges of the vagina and the ligaments gently drawn downwards, a roll of iodoform gauze is passed up to, but not within, the peritoneal cavity, and a sterilised gauze pad placed over the vulva. This pad may be changed as often as necessary, but the roll must not be removed till the fifth or sixth day, when the vagina should be gently irrigated. The patients are generally out of bed by the fourteenth day.

Version three weeks before Delivery.

DR. G. STARKER contends that version can be much easier performed before labor sets in than it can after uterine expulsive efforts have begun, when the uterus resents manipulation by gripping the fœtus more firmly necessitating anaesthetics and the risks of lacerating uterine and fetal tissues. He therefore conjures medical men to examine pregnant patients a week or two before their expected confinement, so as to ascertain and correct presentations, and in illustration of this advice he submits a case where in the inside of ten minutes, and three weeks before labor set in he performed version by external manipulation alone in a multipara, who labored severely at each previous confinement, which was a breech presentation; but after this manipulation she was brought to bed in three weeks' time when the

head presenting in the L. O. A. position the entire labor lasted for 95 minutes, and she was delivered of a girl baby. Her progress since then has been uneventful.

Rules for the Introduction of Instruments into the Uterus.

DR. C. S. BACON says:—

1. Do not expect to complete the preparation of the patient with less than fifteen minutes of hard work.
2. Never make the examination at the first visit of the patient. Instruct her how to take a vaginal douche, and direct her to use sublimate douches twice a day for three or four days. If immediate examination is required, let it be done at her home or in a hospital with all the preparatory details of a surgical operation.
3. Thoroughly disinfect the external genitals and surrounding skin.
4. Disinfect the hands and instruments, including the irrigating tip, which should be a glass tube.
5. Wash the vagina with a solution of lysol or creolin. In the office I have found TOOKER'S bedpan most useful. A liquid soap, like LEE'S or JOHNSON'S, is quite necessary. With two fingers, either with or without sterilised gauze or cotton, thoroughly scrub every part of the vaginal wall.
6. Introduce a NEUGEBAUER speculum, which is better than any form of CUSCO'S bivalve; for it is asepticizable, and better than a cylindrical speculum, for it is much easier to work through.
7. Disinfect the cervical canal by means of a cotton swab, using first the liquid soap, then strong creolin solution, and finally alcohol. Never introduce an instrument without seeing the cervical canal.

I believe that the carrying out of these rules will prevent all except post-partum, post-abortion and gonorrhoeal endometritis and salpingitis.—*American Jour. of Obstetrics.*

The Importance of Menstruation in Determining Mental Irresponsibility.

KRAFFT-ENING reaches the following conclusions on the subject:—

1. It is useful to consider the mental soundness of women during menstruation from a medico-legal point of view.
2. It is advisable where a woman is held on a criminal charge to ascertain whether the commission of the act coincided with the menstrual period; and by "period" is meant not only the days when there is actual flowing, but those before and after as well.
3. It is best to advise examination of the mental condition when such coincidence is established. This is indispensable when there is a personal history of neuropathic defect of mental disturbance at the time of previous menstrual periods, or when the nature of the act reveals any striking features.
4. When the menstrual process exerts a powerful influence on the mental life of the subject, the accused should be given the benefit of extenuating circumstances in the infliction of the penalty, even although there be no proof of menstrual insanity.
5. When the offence of crime has, in a person whose mind is impaired, occurred during the menstrual period, she must be declared irresponsible, for there is every reason to think the act is due to emotional impulse.
6. But individuals, who by reason of menstrual insanity, would benefit by acquittal on this ground should be considered as dangerous in the extreme and subjected during the times of the menses to close surveillance. It is best to confine them to any asylum for the insane where they will be comfortably cared for and often cured of this menstrual instability of mind.—*Brooklyn Med. Jour.*

PHYSIOLOGY, PATHOLOGY AND BACTERIOLOGY.

Infective Embryonal Pathology.

THE questions to be decided were:—

1. Has embryonal tissue in contact with a certain virus the same strength of resistance as the tissue of an adult?
2. What becomes of the micro-organisms which pass through the placenta and come in contact with the tissues of the embryo?
3. Does the egg not receive the bacilli with the spermatozoid, or are the tissues of the embryo resistant to the development of the bacillus?

The investigation of this subject was undertaken by MAFFUCCI. He inoculated hen's eggs with seven different kinds of microbes and studied them under different brood periods. Under the same conditions, i.e., at different periods of the brood period, he also inoculated the albumen which encloses the embryo. The fecundated and bred albumen is very favorable to the development of a certain series of pathogenic micro-organisms, but the non-bred albumen does not possess this power. The microbes inoculated were:—Anthrax bacilli, spores of cholera of fowls, pneumococcus of Friedlander, fowl tuberculosis, Tuberculosis of mammalia, toxic products of fowl tuberculosis, toxic products of mammalian tuberculosis.

The liver was the most interesting of the organs of the embryo.

By the 10th day the inoculated microbes from the albumen surrounding the embryo penetrate to the tissues of the embryo itself. These infected embryos MAFFUCCI further studied in order to observe in what manner the microbes absorbed in embryonal life would behave in the life out of the egg. The following results were obtained:—

- (1). The albumen fecundated and brooded, taken from the eggs at different brood periods, is a favorable medium for the growth of the above-named microbes; but the same albumen does not induce the growth of these microbes in the living embryo.
- (2). The microbes in the tissues of the living embryo do not multiply.
- (3). Microbes in the tissues of the embryo, which kill the control animal, do not affect the embryo.
- (4). The microbes can be destroyed or attenuated in the tissues of the embryo, but not in the surrounding albumen.
- (5). When the embryo has destroyed the bacillus of the fowl tuberculosis, it is born marmite, and with this form, after a long time, can die without tuberculosis in the organs.
- (6). The same effect of marmite can be obtained by inoculating into the eggs dead bacilli of the fowl tuberculosis.
- (7). The destruction of the virus by the embryo does not render it refractory against the same infection when inoculated later on. In this instance a long time after hatching (fowl cholera).
- (8). Whilst all these changes happen in the tissues of the embryo, the rest of the microbes remaining in the albumen retain their pathogenic power.
- (9). The attenuation of the virus (fowl cholera) appears on the 18th day of the brooding time.

MAFFUCCI next studied the reaction in the embryo of the rabbit with the virus of tuberculosis.

He inoculated buck coneys by the jugular vein, with tuberculosis and examined the semen. From the 25th day to 3 months after, numbers of bacilli were found—and coneys inoculated with this semen became tuberculous. The rabbits born from tuberculous mothers do not present tubercles until the 6th month after their birth, but after this time, they can contain tubercles in the liver and lungs, but without bacilli visible to us. The liver is the great protector from infection, and the living embryo can destroy, attenuate, or communicate pathogenic microbes and develop them later in life.

The Liver and its Glycogenic Function.

DR. PAVY has recently made some rather radical statements regarding the functions of the liver in its relation to sugar and to the pathology of diabetes.

This distinguished investigator asserts that there is no increase of sugar in the blood leaving the liver, that glycogen is not converted into sugar, that sugar does not disappear in the circulation, and that it is all excreted by the liver. The liver in fine has no more to do with sugar than other tissues, and not so much perhaps as the muscles.

DR. D. NOEL PATON, however, in an article on the "Physiology of the Carbohydrates" denies seriatim these views of PAVY, and says that not one of them is proven. "The evidence for the constant production of sugar in the liver," he says "the evidence that glycogen is a source of sugar, the evidence that sugar disappears in the general circulation (I do not say is used in the tissues), is overwhelming, and thus the glycogenic theory of BERNARD holds its ground unshaken."

DR. PATON further asserts that one of the great functions of the liver is to produce sugar will not, at the present time, be denied by any physiologist. The theory of PAVY, repeated in nearly every text-book, that the liver is a sugar-destroying and not a sugar-forming organ, rests on so unsubstantial a basis, and has been so completely refuted by the work of SEEGEN and other investigators, that it need not be considered.

When experts disagree, it is difficult for those who are not in possession of special physiological knowledge to decide. We trust, however, that the truth will soon be reached, for there are few questions of more practical interest than that of the physiological chemistry of sugar.—*Edin. Med. Jour.*

Physio-Pathology of Chlorosis.

MURRI thinks that most children who appear nothing more than a little anemic are potentially chlorotic, and that when abnormal stimulation of the utero-ovarian functions occurs at the onset of puberty, leads to defective nutrition of the red corpuscles, unstable intravascular pressure and other disturbances in the normal blood distribution. Chlorosis manifests itself, and this same may occur, whenever any other psychical stimuli produce results similar to the above. Cold, fatigue, agitation, suppression of menses, &c., may either provoke or aggravate chlorosis in potentially chlorotic subjects, whose central vasomotor nerve systems being notably unstable and any disturbance of such centre must lead to faulty blood distribution.

Anæmia with Cord changes.

A PATIENT, aged 50, suffering with great anæmia, weakness, headache and poverty of hæmoglobin in her blood, was placed by DR. H. M. BOWMAN under arsenic treatment on which she made a rapid recovery; but some months later she relapsed; and, despite the best of treatment, her conditions became gradually worse, the anæmia rapidly increased, sensibility and motive power began to get lost, and the lower extremities paralysed. Ankle-clonus developed, there was incontinence of urine and feces, with occasional troublesome vomiting. Towards the end numerous retinal hæmorrhages were visible, and in six months after the onset of this second illness (or relapse) the patient died. Besides the anæmic state of the various organs the necropsy disclosed an inflammatory cyst running from the head of the pancreas to the duodenum, and the spinal-cord was found to have extensive scleroses most marked in the posterior columns, but present also in the lateral and in the anterior, and wherever the sclerosis was most marked the arterial walls were greatly thickened.

Anatomical Changes in Diphtheritic Paralysis.

DURING convalescence from diphtheria, a male patient, *æt.* 40, exhibited nasal speech, difficulty in swallowing, paresis of lower limbs, ataxy, paræsthesia and loss of knee-jerk. Later on sensory impairment and ataxy of upper extremities occurring—electrical responses normal—respiratory paralysis, carried the man off four weeks after onset of nervous symptoms. The autopsy shewing no changes in the peripheral nerves, but a good deal of degeneration of the root fibres of the cord, especially in the dorsal region, in the root zone of the posterior columns, and in the posterior portion of the lateral columns. DR. BIKELES think these changes similar to those occurring in ergotism and pernicious anæmia, and believes that the resemblance of post-diphtheritic ataxy to tabes is explained by the fact that the posterior roots were affected especially in their intermedullary fibres.

—:—

PUBLIC AND DOMESTIC HYGIENE AND JURISPRUDENCE.

The American President on the subject of a National Health Society.

PRESIDENT CLEVELAND'S message makes the following recommendation to Congress concerning a Public Health Establishment:—

"I am entirely convinced that we ought not to be longer without a National Board of Health or National Health Officer charged with no other duties than such as pertain to the protection of our country from the invasion of pestilence and disease. This would involve the establishment, by such board or officer, of proper quarantine precautions or the necessary aid and counsel to local authorities on the subject, prompt advice and assistance to local boards of health or health officers in the suppression of contagious diseases, and in cases where there are no such local boards or officers, the immediate direction by the National Board or officer, of measures of suppression, constant and authentic information concerning the health of foreign countries and all parts of our own country, as related to contagious diseases, and consideration of regulations to be enforced in foreign ports to prevent the introduction of contagion into our cities and the measures which should be adopted to secure their enforcement.

"There seems to be at this time a decided inclination to discuss measures of protection against contagious diseases in international conference with a view of adopting means of mutual assistance. The creation of such a National Health Establishment would greatly aid our standing in such conferences, and improve our opportunities to avail ourselves of their benefits. I earnestly recommend the inauguration of a National Board of Health or similar National instrumentality, believing the same to be a needed precaution against contagious disease and in the interest of the safety and health of our people."—*American Lancet.*

How "Cognac" is Manufactured.

In a thoughtful pamphlet just issued by DR. SALOMON, "Sur l'Alcool et la Depopulation de la France," I find a recipe for a mixture which, added to any kind of *eau-de-vie*, will import to it the bouquet of cognac. Take mixture of castor-oil butter, cocoanut oil, and other fats, and allow nitric acid to act on it. The product is a mixture of propyllic, butylic, amyllic, palorgonic, acetic, caprylic, conanthylic, capronic, and valerianic acids. Etherify it by the addition of methyl, ethyl, and amyl alcohols, and a product is yielded from 100 to 150 grammes of which will convert a pipe of 100 hectolitres of *eau-de-vie* into cognac. One centigramme of this *cognacogen* injected subcutaneously kills a large dog in ten minutes. One cannot help smiling sadly when one remembers that thousands of individuals pay up to a franc

for a small glassful of this poison, declaring as they sip it that nothing equals a drop of good *fine champagne*, as the stuff is called, for helping a sluggish digestion after a generous dinner. There is surely "death in the pot."—*Paris Correspondent of Lar.*

Bacteriology of Hospital Bed-Cards.

TRONSHOLIAVSKI has positively established the fact that papers that have been in contact with or close to patients are capable of storing up (for future dissemination under favorable conditions) large numbers of pathogenic microbes and indifferent micro-organisms, and that hospital bed-cards afford capital store-houses for these germs of disease, while case-books that have been used at the bedside and then locked away for a year or two also contain microbes to some extent. Sterilised paper could not, he finds, be considered as a germicide, as virulent micro-organisms, when placed on dry sterilised paper, had their virulence unimpaired for considerable time: Thus the comma bacillus retained full vigor for 5 to 14 days on such sterile paper, the diphtheria bacillus for 38, the typhoid for 63 and streptococci for 98 days.

Epidemic of Gonococci Vulvitis: Transmission by Thermometres.

BARNON AND WELL report several cases where recording temperatures per rectum without proper disinfection of the thermometer before introduction to a fresh patient gave rise to an epidemic of gonococci vulvitis which gradually subsided after the order was given to keep all the hospital thermometres soaking in 1 per cent. bichloride solution and after each using to steep them in muriatic acid (1 in 3) wipe them dry on sterilised lint and lubricate with boricated vaseline, because merely wiping the "bulb" with a rag anoluting them with 25 per cent. carbolic solution was by no means sufficient to retard or dispense with the risk of infection.

How to deal with Small-Pox.

THE annual report for 1893 of the health officer for the borough of Stockport contains a short account of the measures adopted by the sanitary department in the face of a threatened small-pox prevalence. There were in all 30 cases in the year up to the end of August, and no fewer than 21 of these were separate and independent introductions of the disease, 10 being tramps. In addition to isolation of cases in hospital thorough disinfection of infected houses and articles was carried out; nine stations were opened for evening attendances for gratuitous vaccination; hand-bills were widely distributed; re-vaccination was urged; the press also lending its assistance, and employers of labor co-operating with the sanitary officers; every common lodging-house was nightly visited, and several cases of small-pox in this way found in an early stage of disease; all cases of illness in these houses were at once made known to the health officer: the inmates were, so far as they consented, vaccinated on the spot; and the medical officer of the workhouse satisfied himself as to the condition of all casuals discharged into the town. It is satisfactory to learn from DR. PORTER that these steps were so far successful that only 9 secondary cases of small-pox arose as a result of the 21 introductions of the disease into the town. The measures adopted are worthy of imitation in other places similarly threatened.

THERAPEUTICS AND PHARMACOLOGY.

Antitoxin in Diphtheria.

As the result of the employment of ARONSON'S antitoxin, in 128 cases of diphtheria treated in the Empress and Empress Frederick's Hospital for children, KATZ reports only 17 deaths or a 13.2 per cent. mortality. From 5 to 25 c.c. of the antitoxin, according to the gravity of the case and the age of the patient were injected just below the scapula and repeated the following day if the child were not better.

Tracheotomy with 5 recoveries was performed on 17 and intubation (all recovered) on 5 out of these 128 cases. The prophylactic value of the antitoxin was shown by the fact that out of 110 of the brothers and sisters, of the affected children, who were given an injection only 8 contracted the disease, and only in a very mild form.

Thyroid Extract in Infantile Myxodema.

IN a recent paper before the American Pediatric Society, DR. OSLER reported successful treatment of infantile myxodema in which the administration of the Thyroid extract produced the happiest results; first, in the entire loss of the cretinoid aspect, in improvement in color, and in the general nutrition; second, in rapid development, as patient had grown four inches in height in a period of fourteen months, and is able to walk and run—before, he had been carried around in the nurse's arms; third, the mental development has been proportionately striking—for fourteen months, his vocabulary consisted of "mama" and "papa," and now he talks fairly well. No one meeting the child for the first time would have any idea that there was anything peculiar about him. Although he is still undernourished and undeveloped, not talking as plainly as an ordinary child of his age, the improvement is very marked and gratifying. He took an amount of extract corresponding to about a quarter of a gland in each twenty-four hours.—*Medical Age.*

Biniolide of Mercury.

P. K. BOLSHESOLSKY strongly recommends biniolide of mercury as an antiseptic in obstetrical and surgical practice. A 1 to 10,000 solution is quite sufficient for all purposes. In normal obstetrical cases the external genitals alone should be washed with the lotion, while in the presence of endometritis free intrauterine irrigations are necessary as well. As the author's extensive experience has shown, the solution affords a valuable means not only protecting the parturient woman from septic infection, but even of cutting short incipient septic processes. In surgical practice he used the biniolide for washing out the abdominal cavity (in laparotomy), pleura (empyema), cerebral meninges (traumatic injuries), and synovial membranes (suppurative arthritis). Although he always used the solution very freely, he never saw any untoward effects, and hence considers the drug "decidedly harmless." Bolshesolsky's favourable opinion of the biniolide is shared by many Arkhangel'sk practitioners, as may be gathered from the fact that the Society, after hearing his paper, he took appropriate measures for placing the solution within the reach of all local midwives.—*Brit. Med. Jour.*

Correspondence.

DR. BAHADHURJI ON MEDICAL POLICY
IN INDIA.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—DR. BAHADHURJI's famous National Congress speech published by him in the *Record* of 16th January, criticising the local medical services, is more conspicuous for its rhetoric and sarcasm than the object which he tries to aim at. Indeed, the whole spirit pervading the speech inclines towards a suspicion of disappointment more than as an effort to improve the status of the classes he championed at the above Congress. It is fully admitted by all right-thinking men that the Civil Assistant Surgeons and Hospital Assistants not only deserve, but demand, a substantial improvement in their professional, official and financial position. The earliest consideration of the Indian Medical Association is, I believe, being devoted to this cause, and if a gentleman of Dr. BAHADHURJI's eloquence and high attainments, acted with more moderation, instead of drawing odious comparisons, he would readily enlist the sympathy of Government in remedying grievances which exist without a doubt.

The Military Assistant Surgeons in former years endured a good deal of hardship, both financially and professionally; the ambition of their goal ended with an Apothecaryship and a retiring pittance at the end. In consideration of this, it was an accepted privilege by them to undergo an extra two years' study to qualify for the Military Assistant Surgeon grade, or in being promoted in their old age to be Honorary Surgeons. Their duties being intimately associated with the army, where many changes were going on, it became necessary for Government to equalise their footing by changing the misnomer of Apothecary—a meaningless expression—by granting them proper warrants and honorary commissions, together with a professional prefix. This comparison was, doubtless, made with reference to the Ordnance, Barrack, Transport and similar departments, and to enable them to exercise the requisite discipline in station hospitals or in connection with their control over the military sick. Owing to this branch of the medical service being purely a military one, Government is very naturally anxious to reserve it for Europeans and Eurasians, as "Tommy Aitkins" objects to be bossed by a native; and, if "John the Christian" to whom Dr. BAHADHURJI alludes, does slip in under false colors or fraudulent conditions, it is unfortunate for the department, and certainly irritating to "Paudyal the non-Christian." This, however, is neither a race nor a religious question, it is abstract policy on the part of the authorities to see that "Tommy Aitkins" is governed by his own kith and kin in matters medical. Hence the Army Medical Staff is an exclusive service. A reserve of Military Assistant Surgeons must be retained to meet the exigencies of the State, and the surplus over requirements has to be provided for. These are drafted into civil employ, and are likely to be returned to military duty at a moment's notice; but those so employed are invariably men of proved ability, capable of doing credit to their appointments. Men with considerable experience in addition to their collegiate training rewarded in most instances for distinguished field

service, or in consequence of being further qualified at home.

In all Indian medical colleges the civil and military students study side by side, the former perhaps having a slight classical advantage, matriculation being so construed. The military student is not called on to pass a test of this nature, yet, as a matter of fact, fifty per cent. have succeeded in doing so, and he only undergoes a four years' curriculum, while his civil friend has to complete, according to the regulations of the General Medical Council, a five years' course. This seems an advantage, but the Military class have to do all the practical drudgery and dispensing of the college hospitals, including night watches; so that taking them all round, the difference is merely one of simple proportions. Omitting exceptions to the rule, there are among civil students graduates in Arts and Science, whose superiority cannot be disputed, but this is a question of money, expended to enhance the position of those who possess these degrees, yet withal occasions have occurred when the military student has competed successfully against his Indian and English-trained brethren in competition for a commission in the I. M. S. Military Assistant Surgeons are nearly all descended from men who have sacrificed life and limb in helping to build up the Indian Empire, the consolidation of which has given security of life and property to all castes, creeds and aliens, and no amount of platform oratory is likely to alienate the obligations of Government from an important and indispensable section of its servants. Surely Dr. BAHADHURJI is not seriously in earnest, when in trying to elevate one class of public servants he imagines he can gain his end by decrying another class in terms of bitter but ill-fitting sarcasm! I believe the very class whose cause he is expounding would be the first to resent any such intention. The military have fought and won, despite the facetious allusion to the "Chief Medicin Militaire" in or out of plain clothes, and if the Civil Assistant Surgeons adopt similar constitutional tactics, there is not a shadow of doubt in Government being unable to resist all reasonable demands, as regards status, pay, pension, or promotion into the uncovenanted grades. Theirs and the Hospital Assistants' cause is a just one. They have waited long in patience with too much silence, and though it may be little consolation, it is a sober fact, that "all things come to him who waits."

The remaining part of Dr. BAHADHURJI's speech *apropos* the professional staff of the Medical Colleges, has an element of truth, in so far that the transfer to military or other duties of a professor, and substitution of another man accomplished enough, but perhaps not in immediate form, is detrimental to "up-to-date" teaching. Whether the Indian colleges be kept supplied with professors from the same source or from without, bears a responsible change to new risks, but doubtless with the profession getting revolutionised almost daily, the selection of professors will have to occupy the serious thought of Government. Irrespective of this, such names limited to "Urbs Primus in Indis" as HUNTER, MACKENZIE, SYLVESTER, COOK, STEADMAN, LYON, HUGHES, DYMCK, WELLINGTON GRAY, and MACONACHIE have tended to make the I. M. S. the backbone of the profession in India.

Lastly, I think a strong protest ought to be sent forward against others, than professors of colleges being allowed

to compete in private practice with the unofficial practitioner, and that professors act only as consultants, as their constant undivided attention to the duties of their own particular branch of work alone makes them specialists, and as such the public should have the advantage of their services as consultants. It is unfair and inequitable for a man in receipt of Government emoluments, who in consequence is able at once to keep up style and appearance, to be allowed to compete with men who have first to make their living before putting on "style," and it is an undoubtedly weak point with patients and others, to surmise that the man who maintains the best trap and horse is naturally the smartest man. Of course the insinuation among non-official practitioners is probably correct that all things being equal, whether it be due to skill or luck, policy or tact, the attention of Government needs directing on this vital matter.

Yours, &c., ALF. MCCABE-DALLAS, L.M., Dub. L.R.C.P. &c.
KUMBHIL; 4th February 1895.

STRYCHNINE AND SNAKE-BITE.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—I have to thank you for your courteous criticism of my paper on strychnine as an antidote for snake-poison in your issue of 1st February.

When I sent my paper to you, I had not expected that you would do me the honor of publishing it in full, but as you were good enough to do so, I regret that you omitted the *tables* appended to the lecture. Since constant reference is made to these tables in the letter-press, their absence renders my remarks much more difficult for your readers to follow. This especially applies to the tables of recorded cases.

With regard to your criticism on the dose of cobra-poison injected, you say that "if more than the ordinary dose of cobra-poison was administered, the experiments are useless."

In this point I was always at one with you, as you will see by reference to my remarks, quoted on the first column of page 80 in your paper in which my address appears.

There I twice repeat the statement that before commencing antidotal experiments I carefully ascertained the minimum fatal dose of cobra-poison.* I also explained that I did this with the object of giving strychnine the fullest opportunity of saving the patient in those cases, where life trembled in the balance. Obviously if an antidote fails to cure such cases, it will be, if possible, more powerless in those where a larger dose of poison has been received.

That I did use the minimum dose, or at least a dose far below that which a cobra would have injected, I think will be obvious from the few following considerations:

A reference to my tables bears out the common experience that there is some ratio between the body weight of an animal and the duration of life after cobra-poison has been injected. In man, death after cobra-bite commonly occurs in from 20 minutes to 8 hours.

A reference to my Appendix (No. II) will shew you that in only two cases did death occur in under 20 minutes, and these cases were promptly rejected as those in which too big a dose had been given. As a rule, you will find the

duration of life ranged from one to several hours, one animal taking over 12 hours to die.

There was a more serious objection, which I had anticipated hearing raised against my paper, *etc.*, that the poison used was exclusively that of the cobra. Since the publication of my first work on this subject, I have been able to remove all fear of that objection, as I have carefully repeated my experiments with Dabola and Krait poison, and have also experimented with Echis. I hope to read a paper on the subject shortly before the local branch, and I think that most people will then be with me in condemning strychnine as a remedy for all or any varieties of snake-poison.

Yours, &c., ROBERT HENRY ELLIOT, M.B. Lond., F.R.C.S. Eng.

Surgeon-Lieutenant, J. M. S.

Acting Professor of Biology, Presidency College, Madras.
MADRAS; 8th February 1895.

(* This statement of Professor Elliot's fully meets our objection on the score of experimental care with regard to the minimum fatal dose: for if the minimum fatal dose be the starting point of our antidotal experiments, we are working on a safe practical basis. But we would ask, what is the minimum fatal dose of cobra venom for a man? The difference, if there be any, and there probably is a difference between the minimum fatal dose of cobra poison, for a monkey, a dog or other experimented animal and man, needs elucidating and definitely fixing, before the utility or futility of an antidote can be accepted as proved experimentally and scientifically. For admitting, as we do admit, an analogy in the lethal action of cobra venom on the lower and higher animal organisms, still this analogy must be bounded by fixed and definite limitations, and before these limitations are demonstrated and proved, the results of experiments on one section cannot in obedience to the simple laws of Nature, or logically either, be held to effect another section of the animal kingdom without a difference.—ED., J. M. R.)

THE BOMBAY MEDICAL COLLEGE AND PRIZES FOR MILITARY STUDENTS.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—The military medical students of the Calcutta Medical College are allowed to sit for honors in all their examinations, and invariably come off gloriously. Those of the Grant Medical College are not allowed this privilege, though they are in every way as good as those at Calcutta, and I am sure would make as good a show if only allowed a chance. The majority of the batch who passed out as Assistant Surgeons for Bengal from Bombay, in September 1894, were matriculated students, who stood in no fear of the University students of their years—1890 to 1894—and the Principal and Professors often acknowledged this fact as an advantage to our class. The first three in the batch, J. V. JAMES, J. W. LAWRENCE and R. H. HART were ready to compete among other prizes, for a special surgical prize presented by Professor W. K. HATCH for clinical surgery.

But Dr. HATCH went on furlough, and the acting senior surgeon thought the prize was only meant for the "civil" students, whereas it was Dr. Hatch's express wish to test the difference between the military and the University students.

The three above-named students got no medals or prizes though they came off successfully in a well-contested examination. The Bengal Government ought at least to allow one medal for the next examination in September 1895 to be computed for by the hands for Bengal, and the Bombay Government might follow suit for the benefit of the Bombay hands instead of leaving us without any encouragement.

Yours, &c., REGULARS JUNIOR.

BOMBAY; 8th February 1895.

THE I. M. A. MEMORIALS ON CIVIL ASSISTANT SURGEONS AND HOSPITAL ASSISTANTS.

I.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—Many thanks to the Council of the Indian Medical Association for taking up the cause of Civil Assistant Surgeons. They have placed us under a deep debt of obligation by their prompt, energetic and timely submission of the memorial on our behalf to the Surgeon-General with the Government of India. God knows how pinched we are, and He will bless the endeavours made to succour us. Thanking the *Record* also for its kindly sympathy and unselfish exertions on our behalf.

Yours, &c., GUNGA GOVINDA SARKARA, L. M. S.
Assistant Surgeon.

NATORE; 11th February 1895.

II.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—On my own behalf, and on behalf of several Civil Hospital Assistants who have rejoicingly talked with me on the subject, I beg to express our entire approval of the action taken by the Indian Medical Association with regard to the grievances of Civil Hospital Assistants and the amelioration of the same. Our heartiest thanks are due to the Council, and we are truly grateful.

Yours, &c., T. N. MUDALIAR, C. H. A.

III.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—Words fail to express my sense of gratitude to the members of the Council of the Indian Medical Association for the interest they have taken on behalf of Civil Assistant Surgeons. The representations of the council regarding our grievances and those of Civil Hospital Assistants are very appropriate and to the point. All should be satisfied and heartily thankful. I now hasten, for my own part and for your readers in these provinces, to thank you and your colleagues for the pains you have taken in laying our grievances so ably and fully before the fountain head of the Indian Government.

We look upon the Council of the Indian Medical Association as a truly representative body, not only of the association, but of the medical profession in India, which we civil Assistant Surgeons and Hospital Assistants can repay only by gratitude.

As money will probably be required to cover incidental expenses, I for my part will be very glad to contribute my own share should a list of subscriptions be opened in the *Indian Medical Record*.

Yours, &c., H. D. PANT, L.M.S.
Assistant Surgeons.

GONDA, OUDH; 5th February 1895.

[* There is nothing to pay. The funds of the Indian Medical Association will meet the trifling expenses of all appeals to Government, but every member of the classes for whom the Association has labored and will continue to labor, will help their cause and the cause of the profession in India, by immediately joining the Indian Medical Association. —Ed., I. M. R.]

IV.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—In cordially thanking you and the members of the Council of the Indian Medical Association for their kind efforts in representing our grievances to the Government of India, I beg to touch upon two or three points raised in the memorials.

Of course first and foremost comes the question of our pay. It is generally argued that the Assistant Surgeons are allowed private practice in consideration of their small pay. Throughout the North-West Provinces, in which I am serving, there are not more than half a dozen stations where there is any income from private practice worth the name. Even in these large stations, the competition between the official and non-official practitioners is so keen that the official practitioners are usually ousted from the field owing to their inability to attend to a patient at the latter's convenience, in consequence of their hospital duty morning and evening. I have myself lost paying patients by my inability to attend upon them during hospital hours. Where there is a choice, the patients naturally give preference to non-official practitioners, who can be called in at any time their services are needed, whereas the time a service man can spare for his private patients is very limited. Those who pay the piper are entitled to call the tune at any time, and they expect the tune played.

In consequence of the inadequate salary we draw, there is always a temptation to add to it by private practice whenever the chance turns up, to enable ourselves and our family to keep body and soul together. If this temptation is yielded to during hours of duty, the hospital work suffers.

By raising the salary of the subordinate medical officers, the Government will considerably relieve their pecuniary anxiety, and they will be able to devote their hours of duty exclusively to Government work.

Admitting that in such large stations the income from private practice compensates for a small salary, what is to console the majority of those Assistant Surgeons who are employed in small stations where the income from private sources does not amount to more than a beggarly sum of Rs. 10 or 20 per month. Transfers to large stations are completely blocked. Those who have once secured them, have become fixtures for life. For unfortunates, like the writer, the choice lies between the proverbial "frying pan and the fire."

At the present rate of pay, we are totally unable to keep abreast with progressing science. The buying of reference and standard books is out of the question, even ordinary books and medical papers are purchased by sacrificing some necessary comforts. In out-of-the-way towns, where we have to depend upon our own resources in times of emergency and no one to consult with, it is absolutely necessary that we should have a well-equipped library of medical books and papers, but the question "How and where-with" haunts us.

About our social hardships we are simply looked down upon. In India, peoples' worth is gauged by the position they hold in Government service, and among the Government servants by the amount of salary one draws. A separate caste of Government servants has come into existence, in which the position assigned to each member depends upon the *hakumat* he possesses or the rupees he draws monthly. The Assistant Surgeons' position in this official caste system may easily be imagined.

2nd. Is it not an anomaly to subject us to the restrictions of the Arms Act when all other subordinates of similar grades in other departments are exempted. We may keep any number of long, sharp and pointed amputating knives, deadlier than swords, we may keep any amount of the

deadliest poisons sufficient to poison the whole district, should we be so evil-minded, but we dare not carry arms! Is it not a reproach on the Government who will trust us with the valuable lives of its subjects and officers, but cannot trust us with a sword or a revolver for self-preservation without our undergoing the expense, botheration, and in some cases the humiliation, of getting a license.

3rd. As to our position in the durbars, &c. The Viceregal durbars seem to have taken a lesson from the official caste system above-mentioned, inasmuch as Rs. 250 per mensem has been fixed as the lowest pass-port pay for its servants for entering the durbars. Assistant Surgeons, as at present paid, can never aspire to the honor of being invited to these durbars by virtue of their position in their service. The scale of pay prayed for in the representation is very modest, and we look hopefully to Surgeon-Major General Rice for his warm and generous support, and trust that he will, as an act of parting grace, be able to induce the Government of India to grant the prayer of an underpaid and long neglected class of Assistant Surgeons and Hospital Assistants before he leaves the field of his life-long labor.

Yours, &c., ASSISTANT SURGEON, N.-W. P.

WARRANT MEDICAL OFFICERS' PROVIDENT FUND.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—As your journal is so widely circulated and read by every member of our Department, I venture to ask your permission to give publication to the following, and I feel sure that the request therein made with reference to the *Record* will be gladly granted.

There have been several letters written under various non-de-plumes to the Provident Fund, once so flourishing, and as these letters have elicited no response, or the much looked for report, which used to be so regularly furnished during the time of the late Mr. E. A. THOMSON, I feel that Captain Wade should submit a similar report without delay. From personal experience I know that a M. W. O. in sub-charge of a station hospital has more than enough to cope with in his office with the multifarious returns and voluminous correspondence, and though he is willing to do other work he is very hard pressed for time, so much so, that I have known several who cannot even indulge in a game of tennis on an evening.

As no one appears to know who is the President and Managing Committee of the Provident Fund, I would ask those who have the interest of the Fund at heart to send your Manager the small sum of 8 annas to enable some one as secretary to send round circulars and call for votes for a new Managing Committee, when the elected secretary would be asked to take over the books from Captain Wade who should now submit a report at his earliest convenience.

I feel convinced that when the members find an energetic man hoist the standard, they will one and all gladly join such a laudable fund, and even those who have not paid for some years may join as fresh members with a small penalty.

In selecting a Secretary I would suggest the following names though there are others unknown to me who may be

as good, if not better. I have also had in view that no one in sub-charge of a big Station Hospital should be named.

Here are the names:—Assistant Surgeons Luke, Hynes, McArdle, Ressurricao, Mason, Victor, Nugent, Mungavhu, Nazareth, Forrester.

Yours, &c., PATER FAMILIAS.

[Surgeon-Captain Wade promised a report, and we shall be glad to publish it when it comes.—ED., J. M. R.]

THE EFFECTS OF ANTIPYRIN AND ANTIFEBRIN ON TEMPERATURE, IN TWO CASES OF ENTERIC FEVER.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—The following observations on two well-marked cases of enteric fever exhibit the action of antipyrin and antifebrin in reducing temperature:—

(1). In *Case I*, after antipyrin, the temperature fell from 101.6 to 99.4 in two doses, and it rose again in an hour and kept on rising, unaffected, in spite of the continuance of the drug.

(2). In *Case II*, the same result was produced; the temperature falling from 102 to 99.8, after four doses of this drug, and then rising and remaining unaltered by it. Antipyrin was continued for five days, and the result proving unsatisfactory, antifebrin was next tried.

The first dose of 5 grs. of antifebrin in each case reduced the temperature to sub-normal in three hours' time and was accompanied by profuse sweating and marked collapse. The dose was accordingly reduced to one and a half grains twice daily, at 9 A. M. and 2 P. M. Under this dosage at 12 noon the temperature in each case was reduced to normal; the second dose however was found not to have the same effect, as by 4 P. M. the temperature had again risen and remained between 102° and 103.8°F. Antifebrin was also discontinued after five days' trial, as it was found to have no lasting effect in keeping the temperature low.

Yours, &c., A. BEALE, Assistant Surgeon.

In Medical Charge R. I. M. S. "Clive."

RANGOON; 16th February 1895.

A MADRAS GRIEVANCE.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—The Government of India have of late been pleased to favor the Civil Hospital Assistants, serving under the Madras Government, with the grant of free quarters or house rent in lieu thereof. The same class serving solely under the Local Boards of Madura, Nellore and Tanjore districts, are not yet permitted to enjoy this privilege, and I would beg to draw the kind attention of the Government of Madras to the omission. These Local Fund men are exposed to the same difficulties and disadvantages as other Civil Hospital Assistants, for whom the free quarters or house rent in lieu thereof has been sanctioned. Will you, therefore, be kind enough to lend your valuable advocacy to the claims of Local Fund Hospital Assistants in the columns of your widely circulated journal.

Yours, &c., A MADRAS L. F. MEDICAL OFFICER.

[We feel sure this grievance needs ample mention to find early redress.—ED., J. M. R.]

REVIEWS.

THE ENLARGEMENT OF THE PROSTATE: ITS TREATMENT AND RADICAL CURE. By C. W. Mansell Moullin, M.A., M.D., Oxon, F.R.C.S. Surgeon to and Lecturer on Physiology at the London Hospital; late Radcliffe's Travelling Fellow and Fellow of Pembroke College, Oxford; and Hunterian Professor at the Royal College of Surgeons. (Published by H. K. Lewis, 136, Gower St., London W. C., 1894. Price 6 shillings.)

The present work on enlarged prostate by Dr. C. W. Mansell Moullin is quite unique in its way, for very few (if indeed any) similar works have preceded it. We do not recollect having come across any within the last two years. We have here the record, with incontrovertible concomitant evidence, of accurate and close observations, coupled with "experimental" or exploratory operations made for the relief and cure of enlarged prostate. The new operation of castration to secure these ends sounds at first alarming. Dr. Moullin does not claim to be the first or only performer of this operation. It was performed for the first time by Professor Ramm of Christiania.

Taking the results obtained and the relief ensured in a remarkably short time, side by side with the new operation as the only safe alternative, it certainly recommends itself, in that it is better to lose both testicles at a time of life when the general power is more or less in abeyance and obtain perpetual and permanent relief, than drag out a miserable existence, longing for death to terminate a series of symptoms that may have lasted for years.

The belief in the purely sexual character of the prostate has led step by step to the undertaking of this new departure in genito-urinary surgery, and certainly if results go for anything, it promises to surgeons an alternative method of treating enlarged prostate well worth a trial, when all other means have failed, always of course with the free consent of the patient, the operation having met with a sufficient amount of success to justify a choice being laid before the patient. The work consists of 167 pages, and is divided into 12 chapters dealing with the normal structure and function of the prostate.

Its enlargement, causes of enlargement, effects of enlargement on bladder and kidneys, symptoms, diagnosis, general and local treatment, radical treatment, consisting of rectal, urethral, perineal and supra-pubic operations, and lastly *castration*. The good effects of castration are said to be observed from the third day, and in a few weeks the patient is cured, the enlarged prostate having atrophied from the size of an orange to a "flat fibrous mass" scarcely discernable. This atrophy is "a change totally different from disappearance of congestion and shrinkage after puncture."

ESSENTIALS OF THE DISEASES OF THE EAR, ARRANGED IN FORM OF QUESTIONS AND ANSWERS PREPARED ESPECIALLY FOR STUDENTS OF MEDICINE AND POST-GRADUATE STUDENTS. By E. B. Gleason, S.B., M.D. Clinical Professor of Otology, Medico-Chirurgical College, Philadelphia; Surgeon in charge of the Nose, Throat and Ear Department of the Northern Dispensary, Philadelphia. (Published by W. B. Saunders, 925, Walnut Street, Philadelphia, 1894. Price 12.)

The work on Otology under review is another of SAUNDER'S excellent "Quiz compends," arranged in the form of questions and answers. DR. GLEASON'S aim in placing such a compend before students has been to enable them with as little preliminary reading as possible to acquire the rudimentary facts of otology. The book is designed to supplement the necessarily brief series of lectures that are usually given in otology during a college course. This aim has been admirably fulfilled in the work before us. It is brief, accurate, succinct, and to the point. The first 19 pages are devoted to the anatomy of the ear, most essential to the right understanding and appreciation of diseases affecting different portions of the aural canal. Next, several *tests for hearing* are discussed, noticing also acoustics and sound. Then come in order, *diagnosis and treatment*, noticing rhinoscopy and pathological conditions of the nose causing ear disease, *examination of patients*, diseases of the *external ear*, *membrana tympani of the middle ear*, *operations on the middle ear*, *miscellaneous diseases*, such as mastoiditis, concussion of labyrinth,—hysterical deafness, syphilis of internal ear, Meniere's disease and diseases of the labyrinth. Lastly a number of *formulae* are appended, most of them original and such as in "the personal experience of the author have proved most efficacious in the treatment of the majority of cases," such remedies as cocaine, alcohol, chinoline salicylate, aluminium, &c. are mentioned, which will no doubt be utilized in this country some day.

The amount of information Dr. GLEASON has conveyed in the 142 pages of his excellent little manual will, if remembered and followed by the physician or student, equip him perfectly to combat diseases of the ear with comparative ease and precision. There are 89 good illustrations added, explanatory of the letter-press, and the paper and printing are all that could be desired.

In noticing any disease, in each case, the pathology, etiology, symptoms, prognosis and treatment are taken up and discussed separately and in the above order, all in question and answer form, enabling the student the more readily to grasp and retain the knowledge thus derived.

THE DYSPESIA OF PHTHISIS: ITS VARIETIES AND TREATMENT, INCLUDING A DESCRIPTION OF CERTAIN FORMS OF DYSPESIA ASSOCIATED WITH THE TUBERCULAR DIATHESIS. By W. SOLLAN FENWICK, M.D., B.S. Lond. Member of the Royal College of Physicians; Assistant Physician to the Evelina Hospital for Sick Children, &c. (Published by H. K. Lewis, 136, Gower Street, London, W. C. Price, 6s.)

DR. SOLLAN FENWICK has laid before us the *summa ultimum* of his untiring and extensive researches on the subject of the *dyspepsia of phthisis* in the work before us. In the eight chapters devoted to its discussion he has accumulated a vast number of facts, the result of original study.

His first investigations were chiefly devoted to studying *post-mortem* morbid conditions of the stomach found in phthisical patients. Later on he observed that not only the stomach but the whole of the intestinal tract exhibited a characteristic inflammation concurrent with the formation of *cavities* in the lungs. These pathological conditions he compared with the former *post-mortem* results and demonstrated two varieties of dyspepsia associated with phthisis.

*The one apparently functional and presenting no histological changes in the stomach, while the other is invariably associated with chronic gastric catarrh." These are recorded in chapters IV and V. The actual connection between organic disease of the stomach and pulmonary tuberculosis, is noticed and briefly discussed in Chapter III. In addition to the above points, the following are also taken up:—Morbid states of the stomach in phthisis, pathology of the gastro-enteritis of phthisis, the dyspepsia of tuberculous children, the variety of dyspepsia which usually occurs in and accompanies the first stage of phthisis, the variety accompanying the final stage and perforation of the gastro-intestinal tract in phthisis. These points are all thoroughly and ably discussed, while the treatment in each case receives a large share of attention.

The contents of these 200 pages are well worthy the perusal of practitioners and senior students, and may be used generally as a work of reference side by side with clinical work in the wards or in private practice. Though not strictly a text-book on the subject of the dyspepsia of phthisis, Dr. SOLLAN FENWICK'S *opusculum* ranks high as a standard work on one of the most important and least understood lesions occurring during the course of that very scourge of diseases—*phthisis pulmonalis*.

Government Medical Gazettes.

GOVERNMENT OF INDIA.

Surgn.-Lieut. Bruce Gordon Seton, who has completed three year's full pay service, to be Surgn.-Capt., 30th Jany.

Surgn.-Lieut.-Col Herbert Boyd, I. M. S., has been permitted to retire from the service, 15th Jany.

Hosp. Asst. Solomon Ezekiel, of the 6th Bombay Cavalry, offe. at the Civil Disp., Fort Sandeman, in addition to his own military duties from the 1st Feb. to the 30th Sept. The service of Surgn.-Capt. W. Vost, M.B., C.M., I.M.S. (Beng.), which were placed temply. at the disposal of the Govt. of the N.-W. P. and Oudh, are placed permanently at the disposal of that Govt.

Surgn.-Lieut. J. Fisher, M.B., I. M. S. (Beng.), Offg. Med. Offr., 35th Beng. Infy., is apptd. temply. to the med. charge of the Bundelkhand Political Agency, in addition to his mily. duties, 28th Dec. 1894.

Surgn.-Capt. C. H. Bedford, M.D., I. M. S. (Beng.), to be med. offr., Lawrence Military Asylum, Banawar, *vice* Surgn.-Lieut. H. M. Earle, 25th Jany.

Surgn.-Capt. W. J. Buchanan, M.B., is granted an extension of leave to 3rd Oct. 1894.

Asst. Surgn. C. A. Owen, in med. charge of the junior grades of the Secretariat Establishments of the Govt. of India at Simla, is granted priv. leave for one month and fifteen days, 9th Jany., and Asst. Surgn. J. W. Hogan, in med. charge of the Army Head Quarters, is apptd. to offe.

BENGAL GOVERNMENT.

Surgn.-Capt. H. W. Pilgrim, 2nd Readt. Surgn., Presdy. Genl. Hosp., to act as 1st Readt. Surgn. of that institution, *vice* Surgn.-Capt. J. H. T. Walsh, from the date on which he was relieved of his offg. duties as 1st Readt. Surgn., Presdy. Genl. Hosp., Surgn.-Capt. D. M. Moir, Depy. Sany. Commr., Metropolitan and Eastern Beng. Circle., to act as 2nd Readt. Surgn., Presdy. Genl. Hosp., *vice* Surgn.-Capt. H. W. Pilgrim.

Dr. Peary Mohan Gupta, offg. civil med. offr. of Faridpur, to be civil med. offr. of the Chitragong Hill Tracts, but will continue to act as civil med. offr. of Faridpur until further orders.

Surgn.-Capt. B. C. Okilham, on being relieved of duties as Offg. Depy. Sany. Commr., Metropolitan and Eastern Beng. Circle., to do genl. duty at the Presdy.

Surgn.-Capt. Narendra Prosnano Sinha, on being relieved of his appt. as Offg. Civil Surgn. of Jessore, to act as Depy.

Sany. Commr., Metropolitan and Eastern Beng. Circle., during the absence, on deputation, of Surgn.-Capt. D. M. Moir.

Asst. Surgn. Narendra Nath Gupta to do superny. duty at the Med. Coll. Hosp. until further orders.

Asst. Surgn. Ram Chander Mousumdar to do superny. duty at the Med. Coll. Hosp., Calcutta, 4th Feb.

PUNJAB GOVERNMENT.

Asst. Surgn. Guranditta Mal resumed charge of his duties as Asst. Chemical Exmr. to Govt. and Lecturer on Midwifery to the Hindustani Class, Lahore Med. School, 15th Jany.

Priv. leave granted to Hosp. Asst. Labha Ram was extended up to the 31st Dec. 1894.

Hosp. Asst. Labha Ram was apptd. to the charge of the Sialkot Jail and Police Hosp. on the 31st Dec., relieving Hosp. Asst. Piranditta, retired.

Hosp. Asst. Ganesh Das, Anandpur Disp., Hoshiarpur Dist., two months' priv. leave, 12th Jany.

Hosp. Asst. Mangal Sam, doing genl. duty at Hoshiarpur, to the Anandpur Disp., Hoshiarpur Dist., 15th Jany.

Hosp. Asst. Suchet Singh, doing genl. duty at Gujrat, was deputed for duty on the N.-W. Ry., Sialkot Section, from the 19th Dec. to the 3rd Jany. He reported himself to Civil Surgn., Gujrat, for genl. duty on the 5th Jany.

On being relieved at the Bhakhar Ry. Hosp., Asst. Surgn. Dalip Singh, Teja, was apptd. to genl. duty at Amritsar from the 28th Dec. to the 2nd Jany.

Asst. Surgn. Dalip Singh, Teja, doing genl. duty at Amritsar, to do sanitation and vaccination duty in the Lahore Dist., 4th Jan.

Hosp. Asst. Imam-ud-din, awaiting orders at the office of Insp.-Genl. of Civil Hosp., Punjab, Lahore, was apptd. to the charge of the Sampla Disp., Rohtak Dist., 15th Jany.

Asst. Surgn. Hari Chand, Sirsa Disp., Hissar Dist., one month's extraordinary leave without allowances, and was relieved on the 17th Dec. by Asst. Surgn. Nazir Hussain, transferred from Gurgaon. Asst. Surgn. Hari Chand resumed charge of the Sirsa Disp. on the 16th Jany., relieving Asst. Surgn. Nazir Hussain.

Asst. Surgn. Parnia Nand resumed charge of his duties at the Gujranwala Disp. on the 21st Jany., relieving Asst. Surgn. Sodhi Karm Singh.

Hosp. Asst. Sobha Singh, doing genl. duty at the Civil Hosp., Rawalpindi, to the Gujrat Khan Disp., 17th Jany., relieving Hosp. Asst. Govardhan Das, apptd. to genl. duty at the Civil Hosp., Rawalpindi.

Hosp. Asst. Ghulam Hyder resumed charge of the Mayo Salt Mines Disp., Kheora, Jhelum Dist., 19th Jany., relieving Hosp. Asst. Phoolle Khan.

Asst. Surgn. Lachman Das, doing genl. duty at Sialkot, to the Leiah Disp., Dera Ismail Khan Dist., 21st Jany., relieving Asst. Surgn. Balia Singh.

Asst. Surgn. Khazan Chand made over Umballa Jail to Surgn.-Maj. L. T. Young, 31st Dec.

Surgn. Capt. C. Duer assumed charge of the civil med. duties of Kurram, 21st Jany., relieving Surgn.-Capt. C. H. Bedford.

Hosp. Asst. Lohoria Ram, doing genl. duty at the Civil Hosp., Ferozepore, was apptd. to the Jail Hosp., Ferozepore, 21st Jany., relieving Hosp. Asst. Masla Bakhs.

Hosp. Asst. Abdul Karim, from the Gobana Disp., Rohtak Dist., to the Okla Canal Disp., Delhi Dist., 27th Jany., relieving Hosp. Asst. Mumraiz Khan.

Asst. Surgn. Nazir Hussain, doing genl. duty at Sirsa, to the Muzaffargarh Disp., 29th Jany.

Asst. Surgn. Sodhi Karm Singh, from Gujranwala to Gujrat for genl. duty, 22nd Jany.

On being relieved of the Leiah Disp., Dera Ismail Khan Dist., Asst. Surgn. Balia Singh reported himself to the Civil Surgn., Mooltan, for genl. duty, 23rd Jany.

Hosp. Asst. Sahaiat Ali resumed charge of the Kamalia Disp., Montgomery Dist., 27th Jany., relieving Hosp. Asst. Sunder Singh.

Hosp. Asst. Govardhan Das, doing genl. duty at the Civil Hosp., Rawalpindi to the Hassan Abdal Disp., Rawalpindi Dist., 27th Jany., relieving Har. Asst. Ram Lal, who reported himself to the Civil Surgn., Rawalpindi, for genl. duty, 28th Jany.

First class Hosp. Asst. Masla Bakhs, doing genl. duty at Ferozepore, is permitted to resign.

MADRAS GOVERNMENT.

Surgn.-Capt. Clarence Forbes Fearnside to act as Suplt. of the Central Jail, Cannanore, during Mr. Young's employment on other duty.

Surgn.-Maj. S. C. Sarkies, six months' furlough.

Surgn.-Capt. G. C. Hall, extraordinary leave for six months.

Surgn.-Maj. R. Ross, I. M. S., 2 months' extension of leave (p. a.)

BOMBAY GOVERNMENT.

Third class Asst. Surgn. Joseph Henry Whittenbury, to be 2nd class Asst. Surgn., *vice* 2nd class Asst. Surgn. White, resigned, 4th Jan'y.

The undermentioned med. offrs. having completed three years' full pay service to be Surgn.-Capt.—

Surgn.-Lieut. William Carr Sprague, M.D., 30th Jan'y.

Miss Annie Walke, L. M. & S., Second Physician, Pestonji Hormasji Kama Hosp. for Women and Children, Bombay, on private affairs for six months, 1st March.

Miss Freany K. R. Cama, M.D., to act as 2nd Physician, Kama Hosp., *vice* Miss A. Walke.

Bai Bakhmabai, L.R.C.P. & S. (Edin.), to act as House Surgn., Kama Hosp., *vice* Miss Cama.

Surgn.-Maj. H. McCalman, M.D., furlough for one year, seven months and twelve days from 9th March.

Miss Freany K. R. Cama, M.D., House Surgn., Pestonji Hormasji Kama and Bamaaji Kadalji Albless Hosps., priv. leave for one month.

Surgn.-Maj. D. C. Davidson to act as Civil Surgn., Dhaniwar, *vice* Surgn.-Maj. H. McCalman, M.D.

Transfers of Hosp. Assts.—Maueklal Manondas, from genl. duty, Bombay, to House of Correction, 30th Nov., and back to genl. duty, Bombay, 13th Dec.

Gopalrao Ramchandram, from Sathana Dispy., to Vagra Dispy., 20th Dec. 1894, *vice* Keshavlal Chhotalal, transferred to Ilav, 1st Jan'y, *vice* Phirozsha Dinsha, transferred.

Daji Dhondeo Joshi, from leave to genl. duty, Bombay, 1st Jan'y.

David Joseph, from Civil Hosp., Thana, to Murbad Dispy., 8th Dec. 1894, *vice* Sayana Balloo, granted leave for one month.

Kassalnath Hari, from genl. duty to Civil Hosp., Thana, 7th Dec. 1894.

Samaldas Nanji, from special duty, Kaira, to genl. duty, Ahmedabad, 30th Dec.

Poonjabhai Thakeri, from special duty to genl. duty, Kaira, 1st Jan'y.

Narayan Vithal, from Khanapur Dispy. to Muddelbilal Dispy., 5th Dec., *vice* Pandurang Ganesh, transferred to Saundatti Dispy., 17th Dec., *vice* Yeshwant Vithal, transferred and granted leave for one month.

Sukharan Bhicaji, from Mundgod Dispy. to genl. duty, Karwar, 16th Dec.

Abraham Shallam, from Kapadvanj Dispy. to Civil Hosp., Mahabaleshwar, *vice* Chintamon Bulal, granted leave for three months.

Dattatraya Gunesh, from Supa Dispy., to Siddapur Dispy., *vice* Ramchander Balaji, transferred to Hausbennur, *vice* Purnashram Nagesh, transferred to Civil Hosp., Karwar, 8rd Jan'y, *vice* Waman Ram, *vice* granted leave and transfer to Panditnath Bhawrao, from genl. duty to Civil Hosp., Dhulia, *vice* Yeshwant Shridhar transferred to Dharangaon Dispy., *vice* Mahadeo Choodamon, granted leave for two months.

Udhev Deoji Power, from genl. duty, Poona, to genl. duty Balmagiri, 17th Dec. 1894.

Mahomed Bahimaukhan, from Civil Hosp., Muscat., to genl. duty, Bombay, 1st Jan'y.

Ramchander Gangadhar, from leave to genl. duty, Poona, 24th Dec.

Kassalnath Anant, from genl. duty, Nasik, to Satana Dispy., *vice* Ganpati Nilobo, granted leave for three months.

Krishnasji Dattatraya, from genl. duty to Civil Hosp., Belgawan, 8rd Dec. 1894, *vice* Govind Janardhan, granted leave for three months.

Jehangir Chahalade, from N.-W. By. Hosp. to Mirpur Bators, 23rd Nov. 1894, *vice* Sataramdas Ramchand, transferred to Kamber Dispy., 30th Nov. 1894, *vice* Joseph Isazal, transferred to Sehraan Dispy., 8th Dec. 1894, *vice* Chahermal Sardesai, transferred to Civil Hosp., Hyderabad, 10th Dec. 1894.

Khismal Hashmatrai, from Umarkota Dispy. to Civil Hosp., Karachi, 22nd Dec. 1894, *vice* Teohchand Lekhraj transferred to N.-W. By. Rnk. Dispy., 29th Nov. 1894, *vice* Bhowandas Hashmatrai, transferred to Mitti Dispy., 16th Dec. 1894, *vice* Choithram Shevakram, transferred to Mehar Dispy., 31s. Dec. 1894, *vice* Hiranand Nanumal, transferred to genl. duty, Shikarpur, 31st Dec. 1894.

Promotions.—Asst. Surgn. Santana Caridade Saldanha, from 22nd Jan'y., to the 1st class, 1st grade; Asst. Surgeon Vincent Edward Fernandez, from 22nd Jan., 2nd class, 1st grade; Asst. Surgn. James Earnest Barton, Macqueen, Asst. to the Surgn. to H. E. the Govr., held independent medical charge of H. E.'s Band Body Guard, and house-hold establt. at Poona and Bombay from 3rd Nov. to 11th Dec. 1894.

Hosp. Asst. Wamon Kassnath, is placed on genl. duty, Bijapur, 29th Dec. 1894.

Hosp. Asst. Chinanlal Mahasankham is placed on genl. duty, Bombay, 11th Dec. 1894.

Hosp. Asst. Luxumon Narayan received charge of the dispy., Mundgod, 12th Dec. 1894.

Hosp. Asst. Phirozsha Edulji Bharucha received charge of the dispy., Satlana, 19th Dec., 1894.

Hosp. Asst. Mahadeo Shankar received charge of the Civil Hosp., Thana, 5th Dec. 1894.

Hosp. Asst. Mahomed Hussein received charge of the Civil Hosp., Muscat, 21st Dec. 1894.

Hosp. Asst. Hari Shriniswas Bichu, placed on genl. duty, Sholapur, 7th Dec. 1894.

CENTRAL PROVINCES GOVERNMENT.

Civil Hosp. Asst. Gokal Pershad, who was under suspension, to do duty under orders of the Civil Surgn., Jubbulpore, 27th Dec. 1894.

Three months' priv. leave is granted to Civil Hosp. Asst. Muridhar, of Umrer Branch Dispy., Nagpur Dist., 20th Jan'y. Civil Hosp. Asst. Gokal Pershad, doing duty under orders of the Civil Surgn., Jubbulpore, is temply. apptd. to the Umrer Branch Dispy., Nagpur Dist., *vice* Civil Hosp. Asst. Muridhar.

Three months' priv. leave is granted to Civil Hosp. Asst. Sheikh Mahomed Ramzan, of the Pandhana Branch Dispy., Nimar Dist.

Civil Hosp. Asst. Ramkrishna Palkaji, doing duty under orders of the Civil Surgn., Nimar, is temply. apptd. to the Pandhana Branch Dispy., *vice* Civil Hosp. Asst. Sheikh Mahomed Ramzan.

Civil Hosp. Asst. Wali Mahomed, of the Arang Branch Dispy., Raipur Dist., is deputed on special duty to the Raipur Fair.

Civil Hosp. Asst. Mahomed Zahurul Huq, doing duty under orders of the Civil Surgn., Raipur, is temply. apptd. to the Arang Branch Dispy., *vice* Civil Hosp. Asst. Wali Mahomed.

Civil Hosp. Asst. Bhondoo Lal, doing duty under orders of the Civil Surgn., Jubbulpore, is directed to do duty under orders of the Civil Surgn., Saugor, for special duty at the Garhakota Fair.

BURMA GOVERNMENT.

Asst. Surgn. F. Bradley assumed charge of the Civil Surgency, at Tiddim, Chin Hills, 5th Jan'y.

Hosp. Asst. P. Raman Menon made over, and Hosp. Asst. A. Jegannatha Pillay assumed, as an additional duty, charge of the Civil Dispy., Bawan, Chin Hills, 24th Dec. 1894.

Hosp. Asst. C. Rookasawmy Chetty left Civil Dispy., Maymyo, Mandalay Dist., and assumed charge of the Police Hosp., Lashio, Northern Shan States, 31st Dec. 1894.

Hosp. Asst. Koilas Chander Palit left Police Hosp., Bhamo, and assumed med. charge of the No. 1. South-East Escort at Bhamo, 13th Jan'y.

G. O. C. C.

Surgn. Lieut. J. N. Macleod, M.B. offg. in med. charge of the 19th Bengal Lancers, to office, as Surgn., on His Excellency's Personal Staff. *vice* Surgn.-Maj. Trehasne, on leave, 1st Dec. 1894.

Surgn.-Capt. E. Wilkinson, leave for three months, (m.c.) Asst. Surgn. Guilford Thoy, I. M. S. is granted three months' leave on med. certificate.

The undermentioned Native Military pupil Thakur Singh having passed his final exam. is admitted into the service as Sub-Hosp. Asst., 15th Oct. 1894.

Surgn. Lieut. E. B. Parry, from the offg. med. charge of the 44th Gurkha Rifles, to the offg. charge of the 42nd Gurkha Rifles, *vice* Surgn.-Capt. H. S. Wood, who exchanges to the 44th Gurkha Rifles.

DOMESTIC OCCURRENCES.

The charge for inserting a Domestic Occurrence is Re. 1, for subscribers, and Rs. 2, for non-subscribers, which should be forwarded in stamps with the announcement.

BIRTHS.

CASSIDY.—On the 24th Feb. at Purneah, the wife of Surgn.-Capt. C. Clemons Cassidy, of a son.

HOLT.—On 24th Jan., at Jansl, N.-W. P., the wife of Surgn.-Lieut. R. H. L. Holt, Army Medical Staff, of a son.

BICKETTS.—On 6th Feb., at St. Lawrence Vicarage, Reading, Berkshire, England, the wife of Surgn.-Capt. W. S. P. Bicketts, L. M. S., 17th Bom. Infy., of a daughter.

DEATHS.

BENSON.—On the 4th Feb., at Mysore, Mary Eden, wife of Surgeon-Lieut.-Colonel P. H. Benson.

GALLAGHER.—On 9th Feb., at Byculla, Bombay, from heart disease, Harold St. Vincent, the dearly loved son of J. Gallagher, House-Surgeon, J. J. Hospital, aged 9 years and 3 months.

SCROGGIE.—On 30th Jan., at Bombay, Elsie Indira, daughter of W. R. Scroggie, Civil Surgeon, Sholapur, aged 6 years.

NOTICES TO CORRESPONDENTS.

Waziristan.—We fear your letter would stir up race feeling. Your position is strong, and ranting cannot hurt you.

A. L. M. (Jalpaiguri).—Appeal to the Vice-Chancellor of the Calcutta University. We think your case, if clearly put, would bring about the desired end. With an Indian degree you may appear at the examinations of any of the British Corporations and be exempt from all but a test in the senior subjects alone. A six months' stay and 3,000 rupees will cover all your needs.

W. H. (Dagshai).—The Provident Fund question receives notice in this issue.

G. W. B. (Bhusawal).—Your medical certificate is perfectly lawful. Tell the office in question you are prepared to submit the legality of the matter to the Indian Government.

J. W. P. (Ganjam).—No general order has yet been issued cancelling the decision of the Secretary of State for India.

R. S. (Agra).—Surgeon-Captain Wade in your city is the Secretary of the Warrant Medical Officers' Provident Fund. Apply to him for a copy of the rules.

S. A. R. (Berberu).—Dr. R. H. Elliot, Presidency College, Madras will, we are sure, be glad to receive the report of your case of snake-bite together with the pickled snake, and we would have much pleasure in receiving Dr. Elliot's opinion on the case.

A. A. R. (Lucknow).—If you are a member of the Association, please send in a full statement of your case to the Secretary of the Association, and it will be laid before the Council.

V. C. M. (Bellary).—The matter as you say is still under consideration. The subject of house-rent for Civil Hospital Assistants is referred to in this number.

F. J. (Lahore).—We trust the correction made in this issue will give you satisfaction.

A disgusted ex-medico (Bombay).—The points you refer to are extremely regrettable. The machinery of reform has been set in motion to some good purpose. Let us hope that in a short time things will much improve.

Referee.—Copy of the index is sent to every subscriber for binding purposes.

P. C. D. G. (Kishoregunge), R. C. (Benares), C. A. T. (Tellicherry), A. L. (Mandalay), A. V. M. K. (Bombay), H. G. (Mussorie), T. H. A. (Gadag), R. K. (Amritsar).—Are all thanked. Their communication will appear in early issues.

ACKNOWLEDGMENTS.

GYNÆCOLOGY AND PÆDIATRICS IN INDIA.

By SURGEON-MAJOR H. PETERS DIMMOCK, I. M. S.,
Professor of Midwifery, &c., Grant Medical College,
Bombay.

BEING THE PRESIDENTIAL ADDRESS IN THE SECTION
OF MIDWIFERY AND DISEASES OF WOMEN AND
CHILDREN AT THE INDIAN MEDICAL CONGRESS.

It is my especial privilege on this auspicious occasion of the first Medical Congress in India to open the proceedings of the section in obstetrics, and the allied subjects of gynæcology and pædiatrics, and it is a privilege which I feel to be one of great distinction and honor to that degree, that I have had some difficulty in the selection of a train of ideas, suited to such a wide-reaching object as our meeting to-day must be—wide-reaching not alone in the sphere of Indian medical science, but also in the consideration of the eagle-eyed public that now watches with ever-increasing interest, proceedings and intentions that bear upon the physical weal and hygienic progress of the people of this Eastern Empire. It is matter for congratulation and joy, that not only the men of India have awakened to the enormous benefit to humanity that skill in these particular branches of Medical Science will convey through the alleviation of pain and suffering and the ensurance of a higher standard of future maturity, but that also the women of India are speedily recognising and adopting the benefits that accrue to them thereby in their hours of difficult travail, in the rearing and healthy management of their children, and in the treatment of the particular ills to which they are so often the unfortunate heiresses.

This happy consummation of philanthropic hopes, this cutting of the gordian knot of the conservatism of custom, has been furthered by the humane sympathy and loving benevolence of the COUNTESS OF DUFFERIN, whose name will be handed down to posterity, particularly in India, as a benefactress of womankind, while her scheme for help thus inaugurated has been and will be still more promoted by the intelligent appreciation and assistance with which the more enlightened men of India have sought and encouraged the bringing of skilled aid to their wives and children into the secluded precincts of the zenana. This ready adoption of means for the relief of such suffering within so short a space of time promises great impetus to the advance of knowledge in the subjects of this section, of which India stands so much in need, and which has from centuries immemorial languished in the most deplorable depths of ignorance and superstition under the peculiar prohibitive customs of the people of the land, and the uncouth and repulsive traditional methods of the native midwives.

As this new light is spread amongst the people by the medical men and women pioneers of our art, we may look forward to a fulfilment of the results of higher knowledge and skill as well as to an appreciation of those efforts that can not only relieve the acutest suffering, but can so often crown the hopes of a happy family.

In our particular corner of the world's work it is our beholden duty—and I am sure it is with most of us our enthusiastic pleasure—to strain our intellects to add to the knowledge that will help on, enlighten, and inspire our fellow-workers; and we should remember that even a little good work done and recorded often goes to the piecing together of a great discovery. The geniuses of every generation who have been led to the exposition of some great truth have mostly gained intuition, aid, and inspiration from the labors of others, past and present, and have based on them their observations and conclusions.

It has been their particular gift to unite these fragments into the whole and to gather the facts of knowledge thus previously worked out, often in an apparently insignificant degree, further adding the requirements that constitute the full evolution of the master mind, and placing them together in the progressive steps of entire and true completion.

So let us ever be certain that as we glean the stray cornstalks in the field of experience, it is in our hands to furnish material for the skilled laborer to bind into goodly sheaves. In searching for a fit subject for this address, it seemed to me better to select matter of some unique interest than to generalise in the many attractive ideas that such a meeting as this would be sure to call up. Indeed, these particular branches of medical art have not progressed in India in anything like the way that general medicine and surgery have done, owing to circumstances to which I have already referred, as well as to the unwillingness of Indian women to enter hospitals, to undergo operations, and to submit themselves or their children to treatment at the hands of male practitioners, and to have given a review of the advances made in these subjects in India would have been a somewhat barren task. One can point to the works of TILT, BIRCH, JOUBERT, and a few scattered records in the various ephemeral Indian medical journals that have brightened the dim history of the labors of the last 50 years, but there has been no attempt to systematise or to establish a permanent literary interest in these branches, such as is the case in the countries of Europe. The second generation of Indian medical practitioners has reached maturity, and still these important subjects are in their infancy with us. There are many parts of them in which we require full and accurate information of special application in India.

In obstetrics it is self-evident to anyone with a modicum of experience that on account of the great variance in the measurements of the pelvis and the development of the child in the different races, the whole gamut of operative manipulations must differ greatly, and such a consideration alone would demand an entire text-book of careful collaborative experience.

A wider knowledge of diseases occurring particularly in women in various parts of the country, with methods of treatment and the results of operation, is much to be desired.

The diseases of Indian children are comparatively an unopened subject, and promise a novel, instructive and extensive sphere of most useful enquiry to those who have the opportunities and advantages, and will take the trouble to record experience in them.

It is time that we awoke from our lethargy. May our meeting of to-day be a trumpet call to workers throughout India for further re-advance all along the line of these particular subjects, and perhaps a suggestion for the foundation of an Indian obstetrical society, similar to the London one, may not fall amiss in this enlightened city, where the torch of progress has been uplifted to light the way of encouragement to a mutual interchange of thought and life.

Posterity demands it as a duty, and women doctors, especially with their many advantages, must not forget that it is our obligation to add to accurate knowledge as well as to relieve suffering.

Now as my mind has for a time been much occupied with some stiff problems in puerperal fever, I decided with diffidence to attempt to record the still imperfect, but extremely interesting, solutions that certain such cases have presented to me.

Since Professor SEMMELWEISS first placed us in possession of the axioms of puerperal fever, there has been accumulated a mass of evidence to demonstrate their truths, and fresh knowledge has been added to them, especially by the discovery of the antiseptic system of LISTER.

But though the ideas of all authorities are fairly well defined, there are still many effects and conditions of puerperal fever and points of difference that are hard to reconcile. This is especially the case in a country like India, which teems with forms of pyrexial diseases that are liable to complicate the pregnant and puerperal states. To indicate all forms of puerperal fever as puerperal septicæmia, whatever the infective cause, and however much the symptoms may vary, is alone sufficiently confusing, when we are brought face to face with their actual protean clinical facts: and, on the other hand, to seek to differentiate each and every kind of puerperal fever according to its features, whether of cause or effect, would lead us into an interminable phraseology that would be too awkward for any practical purpose.

The old familiar term "puerperal fever" as a main distinctive indication is rendered sufficient for all purposes by the affix of a descriptive adjective for the special condition or cause associated with the pyrexia of the puerperium, which after all is the generic meaning of puerperal fever. Thus the words traumatic, septicæmic and pyæmic puerperal fever, would describe fairly well the form of puerperal pyrexia that was associated with traumatism, septicæmia, or pyæmia. Any local effects can, at the same time, be described as complications, and we should thus have a designation like 'traumatic puerperal fever with pyometritis,' and so on.

To eliminate the special characters and peculiarities of these and other complex puerperal fevers, we require a very extensive knowledge of their clinical features, and in India we are confronted with so many kinds of the fever type of disease, that such an enquiry is sure to be full of immensely interesting and intricate possibilities. Clinical observation and deductions therefrom are always most attractive, and have been naturally the principal methods of elucidation of disease throughout all time of medical knowledge. They demand the first attention of the physician, and now-a-days, waited on by pathology and its

youthful hand-maid bacteriology, they are yielding most fruitful results. In these rapidly progressive days we are continually on the outlook for some fresh means of divining the actual causes and conditions of disease, and those occurring in the pregnant state and the puerperium are so environed by their own peculiar accompaniments that there is a separate and special field for the study of them, both clinically and pathologically. In a research into the causes and effects of puerperal fever in India we are confronted, not alone with especial disease entities, but also with the many conditions peculiar to the country itself—of season and meteorological events, of race, of surroundings, of habits, of inter-current disease, and of the preliminary effects of the pregnant state under such conditions, in all of which I can only suggest what a large field there is for philosophical, thoughtful, scientific and useful enquiry, especially to those members of the profession who actually practice amongst the people, and are intimate by race association with their modes of life and other influences.

In this there must be no quackery. "Quackery gives birth to nothing: gives death to all things. We shall not see into the true heart of anything, if we look merely at the quackeries of it: as mere diseases, corruptions with which our and all men's sole duty is to have done with them, to sweep them out of our thoughts as out of our practice. Man everywhere is the born enemy of lies."

In a tropical climate the main influence would, of course, be that of the high temperature of the air, by which all developments and changes are brought about with a greater rapidity, so that the tissues become less stable, less hardy, and so tend to disintegrate quickly, when once a rift is opened in their continuity.

The extreme changes of intense dry stimulating heat in the summer and of a depressing heat that come with the onset of the monsoons, present aspects of variation, apart even from acclimatisation, in the organisms of all who are subject to them, and still more of those whose temperaments are liable to an easy divarication of the physiological equilibrium either towards depression or exaltation. In the pregnant woman we have to consider that there is a call upon vascular, secretory, and excretory powers which react to such influences in accordance with the elastic requirements of each and every functional tension. Dry heat stimulates the circulation, raises the tension of the nervous system, excites greater metabolism, and, if the organism is in any way over balanced, revenges itself for the disorder of its dominant systems by a furious hyperpyrexia confusion of its general processes. On the other hand, moist heat depresses the circulation, lowers the nervous tone, impairs secretion, and further promotes an accumulation of effete substances in the blood either slowly or rapidly, so that morbid effects are easily engendered and with difficulty thrown off. So, too, meteorological changes exert their action in corresponding effects. As examples of the differences of disease types under such circumstances may be taken the sharp attacks of fever which occur in the drier seasons of the year, and the low forms of continued fever and insidious cachexia with engorgement of the abdominal viscera, especially of the spleen, such as take place in humid states of the atmosphere and climates.

Frequently the slow development of malarious cachexia produces in the pregnant woman a form of pernicious malarious anaemia, which is characterised towards the end by intense anaemia, oedema, and an enlarged spleen and liver, for the sluggish circulation and nervous debility encourage congestion of the organs.

Race may shew its influence in the various tendencies that are developed out of evolutionary characteristics, as for instance the neurotic type rendering the woman more susceptible of nervous impressions and reactions, often altering the characters of disease by super-added nervous phenomena, such as high temperature quickly subsiding. Habits of food, of drink, and of luxury are worthy of reflective consideration, and it may be accepted as a fact that pregnant women, whose food is of a vegetable and unstimulating kind, will, have less stamina in enduring prolonged pain and exhaustion, but will recover more quickly from ordinary trials, than those whose food is of a more generous description, while again the latter will be more liable to inflammatory reactions and rapid tissue changes, such as sloughing from traumatic injury.

The surroundings of pregnant and puerperal women are manifold in their effects, and include those of the room, the house, the village, and the town, septicæmic, zymotic, and malarious puerperal fevers being the most likely outcome of dangers from these sources.

I have had the usual experience of most enquirers in being baffled at the outset by forms of puerperal fever that I have had to deal with in India, and what impressed me most in the first instance with some of the cases was their unusual and surprising resistance to rigid antiseptic and aseptic precautions. A study of a series of temperature charts, and the effects of various treatment on the temperature, gave the true line of explanation. When once the clue was given, the opening of some of the hidden processes was shewn, so that I venture to tabulate certain forms of complex puerperal fever as follows:—

1. Malarious intermittent puerperal fevers.

(L) Quotidian.

(B) Tertian.

(Y) Quartan.

2. Malarious remittent puerperal fevers.

3. Thermic do. do.

4. Dysenteric do. do.

5. Syphilitic do. do.

I have no doubt that others will be added to their numbers as the science of medicine progresses, and wrests from the chaos of uncertainty the many forms of Indian fevers.

The protozoic causes of these fevers may develop in the pre-pregnant or the pregnant state, and be carried on into the puerperal state to be further impressed with a septicæmic pyrexial element, which is the result of the condition of the tissues and systems of the puerperal patient rendering the unusual secretions and excretions more liable to the action of infective agents. Or these causes may be latent in the system, manifesting no symptoms until they are excited to action by the onset of labor, or roused to a more powerful influence by a septicæmic pyrexia.

To deal with the group of the malarious forms of puerperal fever I submit cases with their accompanying charts. Many of you may be familiar with an experience that pregnant patients in this country who contract malarious fever, or whose systems are inoculated with its organism, are very resistant to treatment for malarious fever or cachexia; either because the blood and tissues of the pregnant woman are very retentive or reproductive of the disease factors, or because they are specially vulnerable to and ineffective in repelling their ravages. How often it happens that a pregnant woman suffering from malarious fever is treated by all the known methods, which produce no yielding of the fever for some time, and when the pyrexia runs high, miscarriage is sooner or later brought about. The quinine may here be wrongly blamed for the mishap, which was in reality due to the ever-heated blood current and to the poisons circulating in it, and I have elsewhere protested against this shibboleth of the objection to use quinine in doses that are adequate for the control of the disease. At the same time we must not forget that sometimes malarious fever is not affected by quinine, and that the system may also be inoculated with previous treatment by that drug, so that it fails to give the expected result.

It may be some days even before an ordinary attack of ague in a pregnant woman can be controlled, and if the case is allowed to go on without treatment, the disease gets such a grip of the patient as to be uncontrollable, and if labour or miscarriage results, an additional puerperal septicæmia is an inevitable result.

We are also all familiar with the sudden appearance of malarious fever coincident with a severe shock to the system, such as a fracture of a bone, the passage of a catheter, or an overwhelming emotion, and recollecting that the dilatation of the os uteri is often accompanied by a rigor, I have attributed the sudden accession of a high temperature at the commencement of labor to a disturbance of latent malarious poison by the vascular, nervous, and tissue changes wrought by the mechanical process of dilatation.

It is difficult to account in any other way for the sudden appearance of these fevers at such crises, when they have not been preceded by any signs of a taint lurking in the body, and I believe that the organisms are really latent, and that their sudden activity is because the balance of nervous control is disturbed by the event of labor, the vitality of the cells and leucocytes are diminished, and their ranks are thereby thrown open to the invaders, because the reflex irritation to the nervous centres causes through the trophic nerves changes in the metabolism of the body, and through the sympathetic nerves changes in the circulation, which facilitate such morbid processes. It is the same with malarious fevers that develop after labor in association apparently with the stimulus to the plasmodia of slight or severe puerperal septicæmic pyrexia, and in these instances the puerperal fever will be established with the thread of malarious fever running through it and giving a distinctive character to the temperature record, for the treatment of which complex condition it is necessary to combine methods applicable to both the diseases.

Further, whenever malarial fever is developed in the puerpera, there is a liability to what may be called an *exogenous* form of septicæmia as a result of the high temperature of the malarial fever, for the lochial secretions decompose rapidly within the genital cavity, and their poisons are absorbed into the system, so as to produce the usual septicæmic effects in addition to those of the malaria, and thus to cause a continuance of pyrexia during the intervals that would be remissions of the malarial fever, and to exaggerate the high temperature of the pyrexial stage of the malarious attack. Very high and alarming temperatures are developed in this way.

Again, puerperal women who have malarial cachexia may have progressed favorably even beyond the first week, when they expose themselves to a chill, and this is followed by the typical phases of the rigor, of the pyrexia and sweating stages of ague. The lochia become offensive, the temperature is continuously high, and there is an intermittent recurrence of the ague and increased pyrexia. It takes several, sometimes many, days before recovery is brought about, while if proper measures are not adopted, the case may end fatally.

In all these cases, associated with malaria of whatever kind, we have not only general effects to deal with, but also those local effects that are inevitably associated with the traumatism of labor. The lowered vitality of the tissues makes them very prone to take on a sloughing or even gangrenous character, and such conditions are not only resistant to repair, and will heal slowly, but add a further and serious danger to the case from a multiplication of poisonous agents. If no treatment of the constitutional state is adopted, their ravages will increase to a terrible extent, so that I have seen cases of malarious cachexia in the puerpera where the genital passages have been in a gangrenous state throughout their whole area, consequently when artificial traumatism is produced by the use of instruments, particular precautions are necessary to guard against such effects, and although there may be no apparent symptoms, most rigid attention should be paid to the local antiseptic treatment. Another effect of malarious cachexia and of malarious fever during pregnancy is to cause a placentitis from which the placenta becomes adherent, and so adds a further danger to the case at labor time. The shock of manual detachment may set up the pyrexia of malaria, or there may be infection from without by the operation. Such patients often complain of excessive tenderness over the uterus during pregnancy, which is no doubt due to the inflammation that is going on. Another effect of malaria in the puerperium is to produce intense neuralgia of some of the sexual organs. It may be the uterus that is thus affected, in which case it is probably caused by some inflammation of the nerve filaments communicated from a placentitis, or an actual primary neuritis of malarial origin, and the patient may suffer great pain, especially in connection with the after-pains. I have found the uterus in these patients to be excessively tender, and the condition has mostly yielded at once to quinine and anti-neuralgic drugs. I can recall one case of acute neuralgia of the ovary which followed a miscarriage. The patient did well in all respects, except that at a regular hour every afternoon she suffered from acute agonising

pain in the left ovarian region. It yielded at once to large doses of quinine.

Post partum hæmorrhage is also very likely to occur, mostly from the effects of the placentitis, but also in consequence of the state of the blood, of lightened blood pressure, and of the defective contractile power of the uterine muscular tissue.

Diarrhœa is a frequent occurrence, and is of great importance. In all conditions of health or disease in people living in India, whether native or acclimatised, there is a primary climatic potentiality towards diarrhœa. A chill, an irritant, or disease are likely to be accompanied by it in ordinary individuals, and in puerperal fever, particularly, this natural tendency is exaggerated by the secondary morbid and derivative tendency of the system to relieve itself of the toxæmia through the mucous membrane of the intestines. Accordingly, the usual dose of castor-oil will frequently start a severe diarrhœa and sometimes almost choleric symptoms are caused by what seems a slight cause. Rheumatism is an occasional complication; the connection between rheumatism and malaria is outside the present subject, so I will not discuss it.

Mania is also a not infrequent sequel, and has partly to do with the state of health and partly with the high temperature. The higher the temperature, the more likely are the psychological centres of the brain to be injured, and disorders connected with them to follow.

The fœtus is, as a rule, not particularly affected, except in nutrition, and so suffers from fever at birth only in occasional cases, and this is probably due to the resistant and destructive power of the placental structures which thus guard the entry of the fetal area from deleterious matters. A similar result occurs in some cases of syphilis contracted during pregnancy.

"To use too many circumstances, ere one comes to the matter is wearisome, to use none at all, is blunt," and I venture therefore to place the following cases before you to illustrate the circumstances which I have already reviewed. Copies 25-28.

Case 1.—Malarious intermittent puerperal fever.

Gaya, a Hindu Brahmin, I para, aged 20, was admitted for slight fever on the 25th June 1892. Confined on the 29th June. Rise of temperature on the second day of the puerperium, which soon developed an apical periodic character. No marked rigors. Antiseptic treatment, and antipyrin were at first tried. On the 8th day quinine sulph., grs. xv., and the motions became frequent and dysenteric in character, while six round worms were passed. The round worms probably helped to set up irritation in conjunction with the other symptoms. The temperature also fell for a short time, but again rose the next day. Eucalyptus was then given internally, but with no appreciable effect, and quinine was again given by the mouth and the enteritis symptoms increased. Quinine was therefore given hypodermically with a gradual and satisfactory improvement. There was another slight rise on the 30th day of the puerperium, which also yielded to quinine injections, and the patient was discharged well on the 4th August. This chart shows well the persistence of the puerperal fever when accompanied by malarial complication and vice versa, fairly regular intermittence, the

irritative effect of the round worms under conditions of disease, and the instant action of quinine by the mouth. So the hypodermic injections were resorted to. As strict antiseptic precautions were adopted, the chart also shows that unless the malarial fever is overcome, antiseptic precautions will not check the puerperal fever, which receives a continual fresh impulse from the malarial pyrexia.

Case 2.—Mild puerperal fever and malarious cachexia.

Two hourly chart.

Jai Babaji, Hindu, 9 para., age 40, admitted on the 25th.

The waters had escaped and the os was fully dilated on admission. The patient stated that she had been in labor for three days and that pains had been severe. Second stage prolonged, presentation vertex, 2nd. The placenta was adherent and had to be removed by manual detachment. The case has the following peculiarities—some degree of traumatism from prolonged labor, and artificial interference at third stage, a consequent mild septicism and traumatic fever, and malarious intermittent fever with offensive lochia.

On the 1st and 2nd days of the puerperium there was slight feverishness. On the 3rd and 4th day marked fever. On the 5th day a sudden and acute rise of temperature of septic origin probably. This started the malarious organisms into active influence, and a daily intermittent temperature followed.

Quinine was not administered until the 8th day, and controlled the fever for a day or two. The lochia still continued somewhat offensive, and the fever recurred on the 12th, 13th, 14th and 16th days. The quinine was steadily continued and arsenic was given on the 17th day. The patient was also treated with antiseptic uterine irrigations, ice-bag over the hypogastrium and uterine oxytocics, and this local treatment no doubt controlled the effects of slight septicism and traumatism. The quinine controlled the malarious fever well at first, but did not prevent recurrence. The effects were, however, aided by the arsenic, for the fever would otherwise have recurred after the 19th day, and the patient recovered completely. Without the antiseptic and antipyretic local treatment, the fever would have developed to a more serious degree, and quinine alone would not have had much influence on its course. At the same time, I believe larger doses of quinine, or hypodermic injections would have cured it quicker.

Case 3.—Puerperal and quartan intermittent fever.

Mrs. C, aged 36, European, 8 para., was admitted for puerperal fever. She had been confined 12 days before admission, and forceps had been used for inertia. The patient had been suffering for some time from mitral regurgitation, and there was a good deal of oedema and anæmia associated with the pregnancy. She had also been residing in a malarious district, and had fever frequently; the fever developed on the 3rd day of the puerperium, had been high, still fairly continuous, and on some days had been much more severe than on others. As the patient's condition was desperate, she was brought to hospital. On admission she was in a very dangerous state, delirious with much dyspnoea and distress, and high fever. The treatment was at first directed to measures for reducing the fever, and the local puerperal congestion by an icebag to the hypogastrium and to the head, and vaginal douches,

ice pack, &c. The day after admission the temperature went up to 106°, and the patient's condition was most grave, her breathing being stertorous, at the time of the highest rise, and she was cyanosed. On the 15th day the temperature went down and the patient seemed much better, but on the 18th day it again rose to 106°, so that the chart gives the indication of a quartan type of fever. This second high temperature wave is accompanied by a rise of the pulse and respiration, which shew increased exhaustion and dyspnoea. Quinine, arsenic, and digitalis effected a cure. The slight rise of temperature of the 25th was transitory, and did not recur.

Case 3 A.—This is supplementary to No. 3.

Mungula Govind, Hindu, para., aged 24 years, admitted 31st August 1894, suffering from anæmia, oedema, and ascites and in great distress. She was pregnant about six months. The liver was much enlarged, and so also were the glands of the neck, and there was a rise of temperature every evening. The patient improved much under treatment, principally of arsenic and quinine, and was confined on the 12th November 1894, labor being normal. The chart shews slight septicæmia from the 4th to the 11th day of the puerperium, which apparently yielded to antiseptic treatment, but was followed on the 12th day and afterwards by an intermittent tertian fever, which did not yield to quinine by the mouth. When quinine was given hypodermically and Liq. arsenicalis also prescribed, the patient had two deferred attacks of fever and then recovered.

Case 4.—Puerperal remittent fever.

Daice Lalce, aged 35, Hindu, 6 para., admitted into hospital for fever. Temperature on admission 103° F. Pregnant at full term, and evidently much distressed. She had suffered from fever during pregnancy, but more especially during the last ten days. She complained of uterine pains. On the morning of the 3rd day after admission the pains became more severe, and she was confined the same day, the temperature being persistently high throughout labor. The notable points in the chart are as follows: The sudden fall of temperature on the 2nd day after the quinine grs. v. sub-cutaneously. The fall was very marked, and the temperature rose again on the 3rd day to a very high degree after a rigor and remained high. The rigor probably indicated dilatation of the os. After confinement on the 4th day after admission, there was a very alarming fall of temperature after the administration of sodii salicylatis during the fever and quinine sulph. grs. xv. no doubt due to the drugs, to exhaustion after labor, and to the usual fall of a temperature of the remittent type.

After this day of considerable danger a condition of puerperal remittent fever was apparently established, and influenced here and there by the treatment. The effect of sodii salicylatis in depressing the temperature and vitality is marked and peculiar. The patient developed meningeal symptoms on the 25th day of the disease, to which she rapidly succumbed. Previous to this date, I think the chart shews that the fever was greatly controlled by the quinine given hypodermically. In spite of the severity of the case, the fever line does not range high during the last week, and the case might have progressed more favorably if the patient had not been exhausted by neglect and want of proper attendance before admission.

The treatment of these malarious puerperal fevers has been frequently shown in the clinical memoranda. It consists mainly of unusually thorough antiseptic measures for the genital passages and uterine cavity, of general and local antipyretic agents, i.e. in various ways being particularly useful, and of internal antiseptics, while the malaria must be controlled by its specific drugs, quinine, arsenic, &c.

In desperate cases of hyperpyrexia, the ice pack and the immersion tank are of signal service.

The method of administration of quinine has received particular attention, and I was so disappointed with it when given by the mouth, that I have almost abandoned it entirely. It is certainly of no use, except in large doses, but in puerperal septicaemia, I have pointed out that there is a potential irritability of the intestines which is likely to result in diarrhoea, and these large doses of quinine have invariably been followed by diarrhoea and even by enteritis, and if there is diarrhoea already present when the quinine is given, the drug may increase it so that even severe collapse may follow. No one can doubt that quinine is an irritant to a certain extent to the digestive tract, for it will often cause dyspepsia, urticaria, gastrodynia and other symptoms of this kind. I therefore give it in large doses of 5 grains or 10 grains subcutaneously, and if the latter amount, it is well to have a couple of syringes charged with the solution to save time. The injections of course not being made too close together. This effect is seen in case No. 1 in which quinine was given by the mouth on the 8th day and was followed by symptoms of enteritis. It had no effect on the fever, and probably there was not much absorption of the drug. When quinine was pushed hypodermically, the patient improved. The quinine does not exert an antipyretic influence to any great degree in these subcutaneous doses, but is probably more antiseptic and antiperiodic in its action.

The next series of puerperal fevers is that of the dysenteric form, which arises in connection with true dysentery attack. The dysentery itself generally originates during pregnancy either at full term or earlier. In the former labor and in the latter case abortion or miscarriage is very likely to occur, and so we have a puerperal condition with the dangerous concomitant of very poisonous alvine discharges. Infection of the genital passages from these produces an extraordinary disease of the puerperal fever type.

Case 5.—Puerperal fever and acute malarious dysentery.

Yelloo, Hindu Kammy, resident of Parel, a malarious unhealthy suburb, was admitted into hospital on the 1st July 1892. Suffering from dysentery from which she had been ill for a fortnight. These facts were only elicited after she had been admitted into the general ward, and she was then isolated. Labor set in the day after admission, and was quickly over, the process being normal. Up to the time of labor, she had eight motions. They were scanty, containing a good deal of mucus. The progress of the case is indicated in an interesting manner by the chart, and I draw attention to the line of temperature record, which for the first six days does not range high. At the same time I think there was a faecal injection, for there

is during these days a distinct inclination to an apical temperature indicating slight puerperal fever. Also the number of motions increased greatly and undoubtedly exercised a derivative effect. On the 22nd day of disease, the 8th after admission, there was a sudden and high rise of temperature. This was the result partly of puerperal fever, but no doubt it was to a large extent due to the malarious taint of which the dysentery was a primary expression. There were irregular recurrences for the next three days, until the 26th, when Quinine Sulph. xx grains having been administered by the mouth, the number of motions increased and the patient was collapsed. The hypodermic treatment by quinine was at once resorted to, and the result was satisfactory. This case shews conclusively how irritating quinine administered by the mouth in large doses is in such cases. At the same time, unless the malarious taint is overcome, the case is sure to go from bad to worse, nor will the dysentery yield until the malaria is subdued. Evidently the hypodermic treatment is the mainstay of these peculiar cases.

Case 6.—Dysenteric infection and puerperal fever.

This is an extremely interesting case. It was coincident with the case of Yelloo, No. 5.

Mrs. W., Eurasian, 1. para. aged 23, admitted on the 24th June 1892 for pregnancy at full term. She had suffered somewhat from morning sickness, and had oedema of the lower extremities. Labor set in on 2nd July, the same day on which Yelloo No. 5 was confined, and they were in adjacent beds. Labor was tedious and forceps were applied. There was some laceration of the perineum. On the 3rd day of the puerperium, the patient was attacked with fever which soon assumed a peculiar character, the patient being in an unusually prostrate state, and the bowels shewing a tendency to enteritis. Antiseptic and other methods of treatment were adopted. On the 5th day diarrhoea set in, the motions shewing the character of muco-enteritis. On the 9th day as the diarrhoea had not been quite so bad, 20 grains Quinine Sulph. were administered by the mouth with the alarming result shewn on the chart. The diarrhoea became violent and uncontrollable, and the effects were choleric in their great intensity. After the patient had recovered somewhat, I began to give quinine subcutaneously and she recovered.

From these two cases, and from subsequent experience, I have observed that there is a particular form of puerperal fever associated with dysentery, the peculiarity of which is an increased tendency to elimination by the bowels which may go on to actual enteritis, and that the fever is allied to the malarious intermittent form of fever. Possibly the infective agents of dysentery and malarious fever are analogous. It is certain that the decomposing products in the intestines would predispose the system to an infection of this kind, but their actual absorption into the blood is necessary for the development of puerperal fever from them, and this is effected through the genital passages.

Dysentery itself is very obstinate in pregnant women, and there are no doubt turgescence of the mucous membranes and changes in the circulation which make the disease persistent. It is also desperately resistant to remedies, so that a dysentery of an acute form in a woman near the end of pregnancy is peculiarly dangerous in this

respect as well as from the further risk of exciting premature confinement and of following up its primary havoc by an infection of the system with the fecal toxins.

The most careful treatment often fails to prevent these consequences and sometimes, when the case has taken a favorable turn, it is liable to relapse. Much may be accomplished by repeated large doses of ipecacuanha, opiates, sedatives, antiseptics, internally and externally, and ipecacuanha is sometimes very well borne; so that I have been able to give 80 grains twice a day. No treatment is effective unless the food is absolutely unirritating, and peptonised milk and lime water is the only diet that serves the purpose.

I have included an example of another series of cases, those of the syphilitic, because I have found peculiar results in the puerperal state in women who are strongly tainted with the specific disease.

Case 7.—M. M. aged 20, Hindu, I. para, admitted in labor on 26th April 1894, and in consequence of a tedious 2nd stage, vertex. 2nd, was delivered by forceps on the morning of the 27th. There had been no complication of pregnancy, but the patient had appearances on her body which indicated syphilis. On admission the temperature was 102.5, and the pyrexia continued after delivery. The case was treated antiseptically for simple septicæmia, and somewhat improved, but again relapsed. On the 12th day of disease Pot. Iodid. and Pulv. Santoniu were given with a gradual improvement, but the patient still remained feeble and prostrate and in bad nutrition, until inunction of mercury was given on the 20th day of the puerperium. The improvement then was rapid and satisfactory, and the patient was discharged well on the 11th June.

This case suggests many questions.—Why puerperal fever should develop under such conditions, and whether it is puerperal fever,—whether it is a climatic effect on the syphilitic patient, whether the syphilis stirs up an irritative fever in the system—or does the syphilis render the body more susceptible of septicæmia, and the septicæmia more persistent than usual until specific remedies are used? In cases of puerperal fever of a continuous type associated with increasing cachexia, where the child shows also faint symptoms of congenital syphilis, it is always advisable to administer specific remedies. Of other forms of Indian puerperal fever the thermic is the one most frequently met with, and of course its main characteristic is intense and resistant hyperpyrexia. It is usually the sequel of pyrexia occurring before or during labor, although it may occur during the puerperal state, being most liable to happen on the 3rd day in connection with the usual slight fever which results from any infection or bacterial disturbances on that day. It may be associated with puerperal eclampsia, and cases of this kind that occur without albuminuria indicate an intense congestion of the meninges. Complex cases of puerperal fever in association with other diseases of the pyrexial type must sometimes occur, and again, I repeat, if practitioners can give time to clinical records, we may hope for more knowledge of them. Busy men cannot do this of themselves, I know, but with the help of skilled nurses they may gain much useful information, and I would wish to impress upon the profession and the public how necessary it is that there should be an encouragement to the training of nurses of all castes and creeds not alone for

good clinical work, but for the greater work of a more assured wrestling with disease. It has always been the rôle of the profession to teach the public what it requires for its health's sake, and if every medical man would insist on his bad cases being properly nursed, I am sure the public would soon come to recognise how indispensable such nursing is. On our side of India there is certainly an apathy on the part of the public to good nursing in serious private cases that threatens shipwreck to the support of such a scheme, which our nursing schools are trying hard to promote. Whether we are hospital physicians and surgeons, or whether we are in general practice if we are united, and earnest, if we are single-hearted and true to our noble calling in all these matters, we can each and every one of us strive to work for the general good in our own ways. In the selection of the evolutionary lines of our particular pursuits along this great scientific broadway of the most interesting, humane, and inspiring, though often most exacting of life-tasks, we have much to be proud of, to reward and to encourage us, and many good deeds to do. At the same time let us bear in mind

"Ne let the man ascribe it to his skill
That thorough grace hath gained the victory.
If any strength we have, it is to ill,
But all the good is God's, both power, and eke will."

—10—

CHOLERA AND QUARANTINE.

BY SURGEON CAPTAIN P. W. O'GORMAN, I. M. S.

Civil Surgeon, Madnapore.

"QUARANTINE" was originally derived from the Italian word *quaranta*, forty: meaning a forty days' detention or isolation for the prevention of spread of an epidemic disease. It has been defined as—"the enforced isolation of individuals and certain objects, coming whether by sea or by land, from the place where dangerous communicable disease is presumably or actually present, with a view of limiting the spread of the malady. The objects liable to quarantine include—on the assumption of their being apt to carry the contagion or infection of the disease—the luggage and personal effects of the individuals isolated, certain articles of merchandise and ships, and, inland quarantine, carriages and other vehicles. Sometimes entire communities and districts are subjected to quarantine. (HARRY LEACH and SHIRLEY MORPHY) * Ordinarily, the word *quarantine* is colloquially employed to designate any restrictive or detentive measures taken at frontiers or ports of entry, &c., to arrest contagion by land or sea. *Quarantine* may be divided into I *Maritime*, II *Land*. It may further, for practical purposes, be classified into—

(1). *Ancient Quarantine*.—Meaning the unconditional arrest and detention of all vessels or individuals arriving from any infected locality, until, within a minimum of 40 days or less, the presence or absence of the disease was proved by lapse of time.

(2). *Limited or rational quarantine*.—The examination conducted to ascertain the presence or absence of causes of communicable disease, without detention for more time than is necessary to the discovery and the destruction or removal of such causes.†

* Quain's Dictionary of Medicine: Article Quarantine.

† See Antiseptic Marine quarantine: Its theory and practice. Dr. Ashburn-Thompson, Government delegate, New South Wales; Trans. Inst. Cong. Hyg., London 1901, Vol. I, page 54.

(3). *Medical inspection.*—The medical inspection of vessels, railway trains, &c., or individuals coming from an infected locality without detention of "healthy" persons, vessels, &c. "*Infected ships*" &c. (with a case on board or with fresh cases during preceding seven days) are to submit to (a) disembarking and isolation of the sick; (b) the others to remain "under observation" not exceeding five days; and (c) disinfection of passenger's property as well as the ship, train, &c. (d) Emptying of water tanks and pumping out bilge-water after disinfection; and (e) delayed disembarkation of crew. "*Suspected ships, &c.*" (having had cases, but with none during the last seven days) are to submit to (a) medical inspection, (b) disinfection, (c) substitution of good drinking water for stored supply, and (d) pumping bilges dry; the last two before entering dock. In England the "observation" is carried out in the homes of the persons concerned, notification for same being conveyed to the local sanitary authority: pauper aliens and persons from infected ports, who are either filthy or unwholesome, are prohibited from landing. (Orders of Local Government Board, 6th September 1892).

The above is more or less the substance of the agreements drawn up by the International Conference on Cholera Quarantine at Dresden in 1893. Into the relative merits of each class there will be no need to enter. I shall confine myself to briefly offering a few suggestions on land quarantine, as we become acquainted with it in India in its particular application against the visitation of that much dreaded disease—Cholera.

In spite of the advancement of science, the propagation of cholera is still enigmatical—not to say mysterious. It is true we do not now regard the skies for portents and signs, but rather seek them on the earth. From staring at the astral heavens we have come to gaze on the firmament of pathology; and in lieu of viewing cosmic phenomena with telescopes, we bow our trembling heads above microscopes in awe of entirely new and unexpected comets. We have thus now come to regard atmospheric "waves" as mythical, and are asked to pin our faith on the "comma bacillus" of KOCH. But instances still arise to question the wisdom of such absolute dogmatic teachings. *Spe dixit pronunciamientos* cannot stifle enquiry or answer objections wherever legitimate, or if they suffocate them, it will be to the discouragement of science and to the postponement of accurate knowledge that is necessary for the suppression of epidemics, and thus for the advancement of the happiness of mankind. Now, one of the very mysterious things that puzzle the sanitarian is the periodical extraordinary and rapid progression into wide areas, from ordinarily localised or it may be isolated centres, of such diseases as influenza and cholera, in epidemic or still more pandemic form. Previous to the year 1817, cholera, though known apparently from the time of Hippocrates, was comparatively a mild disease, as the history of the Portuguese, French and old English settlers in India have shewn, and any epidemics that occurred were of a very localised character. India for centuries has been famous for her enormous gatherings of pilgrims at the several sacred shrines of Muttia, Benares, Jagannath and Hardwar; and yet we do not hear of epidemics. And although, besides this, the plains and mountains of Hindustan, Afghanistan and Persia have been the theatre

of perpetual war, and vast armies under terrible and plague inviting conditions, unknown now-a-days, have massed and traversed the land from end to end under Maharatta, Rajput, or Mahomedan conquerors, history appears to be absolutely silent as to any such terror-inspiring scourge as must have simply devastated or annihilated many of them had it occurred, and spread havoc far beyond the confines of India in their lines of communication. Cholera in its modern virulent epidemic form was therefore practically unknown until the 20th August of the year 1817, when it appears to have suddenly taken its rise in the Town of Jessore, 76 miles east of Calcutta, whence it rapidly spread (just as in later pandemics) westwards through Calcutta, up the Gangetic Valley, decimating the army of the Marquis of Hastings then operating against Scindia in Central India, and thereafter traversing, during the six years of its prevalence, half the civilized globe, including England. Since then six more cholera pandemics have ravaged the world. How did this first one arise? And why? And why should it sweep the earth as it did? And in days when human intercourse beyond India and between it and Europe was no better than it was before, or for many years after? Again, as Surgeon-Major DUKA, I. M. S., pointed out at Budapest, the other day; if human intercourse alone is the cause of spread, how do we explain the almost endemic and persistent prevalence of cholera near Paris in 1892, and its non-extension to England with every facility for its spread in that direction by sea traffic?

In the recent pandemic still progressing in Europe, can we say that the rapidity of spread can be satisfactorily accounted for by what we know of the life history of KOCH's bacillus? Its incubation, its rapidity of multiplication, and so on? And what are we then to think of those very numerous cases where the "comma bacillus" exists abundantly without producing cholera? And where cholera has been produced without its presence at all? Thus RUMPF in Hamburg, LESAGE and MACAIGNE of the Institut Pasteur, METSCHNIKOFF, LUBERSCH and others, are quoted as having proved that true Asiatic cholera occurs without the comma bacillus; and the negative experiments of PETENKOFFER, EMMERICH, STRICKER of Vienna, HARTERLICK and KLIN that the comma bacillus may be toxic but there is still no positive evidence that it produces cholera.* Klein has written a book† to prove this, and since then has shewn (*Indian Medical Gazette*, May 1893) that similar toxic symptoms are producible, and similar immunity imparted, by the typhoid bacillus of GAFFKEY and EBERTH, the bacillus coli communis and others. That choleraic symptoms are not solely characteristic of Asiatic cholera is, I presume, well-known. English cholera, and ptomaine poisoning from various causes (bad fruit, flesh, fish, rice and so on) are examples. In the year 1887, in Bristol, England, I attended a case with typical symptoms of cholera. I never saw stools more typical, and the only probable cause was unwholesome cheese. There was no cholera in Europe that year, and I regret I had not the opportunity of examining the cheese. Again, in May 1889, in Allahabad, a few hours after my assuming charge of the 13th B. L. I., I attended a native officer suffering from

* Presidential address, Tropical Diseases, Int. Cong. Hyg. 1891.

† The Bacteria in Asiatic Cholera, 1893.

typical cholera symptoms, cramps, thirst, suppressed urine, vomiting, rice water stools and collapse, &c., rapidly ending fatally, although the regiment had only a week before returned from their cholera camp, where they had been sent on account of cases having appeared among them. My suspicions were aroused and the *post-mortem* satisfied me that he had been poisoned with arsenic, and this the chemical examiner soon confirmed. This case suggests great watchfulness during times of epidemic scare, for I suspect such poisonings are more common than is usually believed.

Mr. ERNEST HART claims with great reason, to have established on an overwhelming basis of evidence, collected from every part of Europe, the dicta founded by SNOW and SIMON on the British epidemics of 1848 and 1854, and by himself and RADCLIFFE of the East End London epidemic of 1886:—

(1). That cholera is a filth disease carried by dirty people, to dirty places, and diffused by specially poisoned water.

(2). That you may eat cholera and drink cholera, but you can not catch cholera.

(3). That cholera may be considered for all practical purposes as an exclusively water carried disease, and that it is carried only by water poisoned by human discharges.*

Now these are factors that nobody can scarcely deny, the proofs being overwhelming. But yet though the truth, in my humble opinion, they are not the whole truth. Surgeon General J. M. CUNNINGHAM has traversed them and denied them. But I think that it is important to recognise that although cholera is in the vast majority of cases a "water borne," and communicable disease, yet it is *not always so—not invariably so*—instances to the contrary cannot, I think, be gainsaid.

DR. LANSON, Inspector-General of Hospitals, at the London Congress in 1891, drew attention to the fact that there are now no inconsiderable number of instances of well-marked epidemics having sprung up in limited localities at a long distance from where the disease was already prevailing and among persons who had not been absent from the locality for months, *without it having been possible for them to have had personal communication, either direct or indirect, with any one already affected*, and he instances the investigations by Dr. PARKIN at Southampton in 1856, by Mr. RADCLIFFE at Theydon Bois, Essex, in same year; by Board of Health in New Orleans in 1878; by Mr. FANNEL and Drs. BROUDEL, PROUST and others at Toulon and Marseilles in 1883. *In none of these was there any trace of communication by the sick or by families;† and Dr. LANSON concludes that "the efficient cause of the epidemic of malignant cholera can be conveyed to localities a great distance from where it is already prevailing, in sufficient quantity to generate an epidemic without being carried by man or families."*‡

Again at the recent International Congress at Budapest, Dr. OLSZOW, who has investigated this subject

* Cholera affluens and their suggestion: *Cont. British Institute of Public Health, Edinburgh, 2. N. J. 24 August 1891.*

† Thesis on the transmission of Cholera. Trans. Int. Cong. Hyg. 1891, Vol. 1, page 44, 45 seq.

‡ Thesis on the transmission of Cholera. Trans. Int. Cong. Hyg. 1891, Vol. 2, page 47.

in relation to Russia in particular, says: "After reading some scores of Russian reports and pamphlets and many articles in Russian medical journals, the impression left on my mind is that, so far as the recent epidemic in Russia is concerned, there were numerically more persons who contracted cholera by direct and unguarded intercourse with the sick than by means of drinking water, and that the poison of cholera was less often introduced into a new locality, and less often spread in that locality, by means of water than by persons suffering from the disease by careless contact of the healthy with the sick, and by articles that had been soiled by the dejects of the sick." But although he acknowledges water as the frequent cause of spread, he disclaims asserting that it will explain all that is obscure in connection with the disease. "It will not explain why cholera is one year confined to India and another year spreads to half the civilised globe. It cannot account for every village or town in which cholera occurs."§

Then again, until the year 1890 Influenza was unknown in India and before 1889 perhaps in Asia—What accounts for its origin, virulence and spread in pandemic form throughout India and indeed the world? Inter-communication alone cannot, although eminently communicable by air and water, for this was a great deal better during the Afghan war and yet we had neither influenza nor cholera. If the extra rapid multiplicity of the "bacillus" could account for it, what were the extraordinary favoring conditions? Meteorology apparently fails to answer? And yet in the domain of meteorology, and that of botany or zoology, will very probably be found solutions for many of these problems that at present alarm the ignorant and confound the wise.

We now return again to Quarantine and ask is it never advisable? The ultramontane anti-quarantine party contend that quarantine can never under any circumstances be justifiable, for the simple reason that cholera cannot be kept out of a country because it is communicable by, let us say, "aerial waves" (or aerial currents) which necessarily supersede and abort all such efforts of man; and that therefore our only refuge and hope lie in a good water supply and thorough sanitation. That there is enough ground for this contention I have already shewn. But that this is the whole unexpandible truth is open to question. I am no general upholder of rigid quarantine with its cordons and police, its dodges and evasions, its false sense of security and its neglect of hygiene and sanitation; but I decidedly incline to the opinion that under certain circumstances, a modified quarantine is often perfectly effectual in arresting the advance of disease, even into a sanitarily defective locality. Although this protection is not always evident, it yet occurs frequently enough to demand introduction wherever practicable. Such has been more or less the time worn practice in India, with our army, our cantonments, our jails, and our municipalities. And experience has not proved us false. This modified quarantine is by no means intended, nor in practice is it used, to supersede, hygiene and sanitation; in our first three examples they are nowhere, perhaps in the world, more strictly enforced—but it is an *additional precaution* of great value that the special exigencies of the case demand, and much responsibility is incurred by those who decline to accede

§ Spread of cholera by water, S. M. J. 12th October 1894.

to the dictates of our past experience. In India, and the East particularly, we are bound to take these precautions, for it would be absurd to rely solely on sanitary and hygienic improvements, for we live in a country where they do not exist, and among a people ignorant of the simplest principles of cleanliness. Were we then to wait, with folded arms, until our towns and cities are cleansed and sanitated, and until over population learns to distinguish between idle ceremonial and effectual personal purification, we should have to evacuate the country as an uninhabitable land. And as a matter of fact, there is no nation on the globe that does not uphold some system, however modified, of the principle of quarantine. The following propositions therefore may be enunciated. I propose those, with all due diffidence, as they have been modified from those laid down by the Australasian Sanitary Conference of Sydney, N. S. W. in 1884:—

(1). *The degree of protection which quarantine can afford is inversely as the ease of communication and amount of traffic between the infected country and the country to be defended.*

(2). *Quarantine can best yield a protection commensurate with its cost, only to countries whose internal sanitation is good, and in proportion to the perfection of the same.*

(3). *Countries suffering under defective sanitation may also frequently be more or less completely protected by efficient measure of Quarantine.*

(4). *The function of Quarantine, if it cannot exclude infection, is to lessen the entering number of foci of infection and to take instant measures to isolate, and arrest their diffusion, when entered.*

(5). *Countries where international organisation is not perfect cannot afford to refer the observation of suspects to the Country at large.*

Surgeon-General CUNNINGHAM has said "No case can be adduced in which the exemption of any country can be proved to have been due to quarantine or, admitting that in a case of this kind absolute proof is difficult and perhaps impossible, no instance can be adduced in which there are good grounds for believing that such exemption has been due to Quarantine." With all humility before so eminent an authority, I believe I can adduce at least one instance.

In 1892, after the Hardwar *Mela*, cholera spread throughout India and extending into Afghanistan and Persia, assumed pandemic proportions as it progressed throughout Europe. I was medical officer of the Muskhaf Bolan Railway, in course of construction, and some 6 to 7,000 coolies were collected for work along 18 or 20 miles in the Upper Bolan Valley. The Bolan Pass is about 60 miles long. Even before the Hardwar fair cholera was prevailing in Persia and in Kandahar. On the 25th April 1892, cholera broke out among a camp of, I think 400 or 500, railway coolies at Mudgorge, in the Pishin Valley, and some deaths occurred. Special precautions were taken, and coolies from the affected locality were prevented access to Quetta, and it did not spread there—cholera began also to prevail in the villages beyond the eastern entrance into the Bolan Pass in the first and second weeks of April (as I

discovered), and afterwards spread among the Nomad Brui encampments thereabouts, causing many deaths. On the 21st April, cholera was imported into the Bolan by a Brui *raia*, who however made his exitant of the Pass towards Khorasan by the Gesthari route at the mouth of the Upper pass. I heard this villager had placed his camp in quarantine and he had had several deaths. There were no coolie encampments within 14 miles, so they were not affected. But on or about 26th April, harvesting Brui had infected a couple of large villages (kirta) in the lower Bolan, where up to 15th June, about 55 cases with 42 or (76 per cent.) deaths occurred. At the mouth of the upper Bolan 5 cases and 5 deaths occurred. In the lower Bolan generally altogether (from Pirchowki to Bibinani), including those within the mouth of the upper Bolan, some 92 cases were recorded with 63 or 68·4 per cent. deaths, and these in rather a scanty population. On the 26th May, a case, in a hospital subordinate, who had been ordered on the duty, was imported into Hirok, in the centre of the upper pass, from kirta, and another on the 17th June, by train from Sibi. As I was on the spot both were promptly isolated and every precaution taken and the disease did not spread: they recovered. By special Police arrangements I ascertained, as far as the limited organisation could in non-British territory, that, in 32 villages or stations, from the 25th April, the total number of cholera cases on the Sibi-Hirok Railway line, and villages, immediately around the eastern end of the Bolan, amounted to 453 with 320, or 70·6 per cent deaths. The epidemic extended up to 2nd July, 3 months. On the 28th April the pass was blocked; all travellers coming up the Bolan were reported to have been stopped and directed to go by some other route; but Bruihs from the infected villages, including kirta, were not all removed from the Bolan until the 6th of May, several of them in caravans being turned back even from the upper Bolan, on my representations to that effect. That it was true cholera, with numerous seizures, I satisfied myself by personal visits to numbers of the cases throughout the Bolan. This rigid exclusion from the Pass, especially the upper Pass, where the coolie camps existed, proved entirely and completely successful. Not only did no case (other than the 2 importations) occur in the Bolan here, but none was imported into Quetta, a considerable town and the second largest military cantonment in India, nor into the Quetta District. And this, too, considering the circumstances, was very remarkable, for this year was a notably pandemic year, from what I could ascertain cholera was more extensively and virulently prevalent among the Bruihs and villages than in the year before; there was a far greater assemblage of Afghan, Panjabi and other coolies in the Pass (by no means clean people) than in previous years; and the year before, a probably less inviting and certainly less generally epidemic year, not only had cholera penetrated into Quetta but caused heavy mortality even among the European troops, so much so that Sir ROBERT SANDEMAN has recorded his belief that the mortality that year had been the highest on record in Beluchistan (British and agency), and there were reasonable apprehensions of a return in the following year 1892, when, with the opening of the Bolan works of

course, more favorable circumstances were to prevail. Of course in the Pass sanitary precautions as far as possible were in force, and the water-supply, although from numerous open-springs, was in great part in the higher Pass, also protected by conveyance in pipes. But these do not detract from the prominent facts already stated. Indeed, the water-supply of Quetta is also very good, though the cantonment suffered so heavily the year before.

Thus I claim that through quarantine measures under peculiarly inviting conditions, with preparatory epidemic the year previous and in a pandemic year of great virulence, an important part of British and agency Baluchistan was effectually protected from cholera. And not only this that in contradiction to reports to the contrary, the Bolan Pass and probably Khojak, which it feeds, must be held on this pandemic occasion, innocent of the advancement of cholera towards Kandahar and Afghanistan and thence through Persia to Europe.

II. I may I think, also instance the entire protection of the Samana garrison (of 3500 troops and 3000 followers on the Miranzai hills, after the expedition of that name, in the Summer of 1891 although some half dozen cases did occur in the Valley Camps, on which they solely depended for communication and supplies, I was medical officer in charge of the latter and modified quarantine measures were adopted on convoys from cholera stricken Kohat, and effectual steps taken to prevent importation of the disease hill-wards.

III. A more recent instance is the Midnapore Central Jail, population 900, of which I am medical officer since end of 1893. This year (1894) various important sanitary and other improvements have been effected, and I have besides instituted, as far as practicable, special quarantine-like isolation measures on new prisoners, besides careful supervision of town supplies, to minimize the possibility of importation of infectious disease. The results are given below compared with the adjoining town of 32,000 inhabitants.

| Years. | Cholera Cases. | | Cholera Mortality. | | Total Mortality. | |

* Prisoners moved into cholera camp.

† There were besides numerous choleraic diarrhoea cases (non-fatal).

A very few white diarrhoea cases (non-fatal).

‡ Up to October.

§ Up to 15th December 1891.

The last two instances are however founded on reasonable presumption.

The case of Beluchistan is, I think, established.

The promotion of administrative officers to the rank of Surgeon Major-General will henceforth be carried out under the auspices of a specially constituted Promotion Board, of which a general officer commanding a district will be president and two Surgeon Major-Generals members. We understand that the Board will sit at a very early date.

TYPHOID FEVER AMONGST NATIVES IN INDIA.*

By RAM KISHEN, L.M.S.

Medical Practitioner, Amritsar.

It has been repeatedly said by some of the most eminent members of the medical profession in this country that typhoid fever is very rare amongst Indians, and that the indolence is due to their not eating meat or eating it in very small quantity.

During the nineteen years of my professional life, I have worked in Sonapat, Delhi, Lahore and Amritsar, and have seen many cases of typhoid fever amongst natives. I find that many of the people suffer from it in a mild or severe form, at some or other period of their life, and it is not consistent with the result of my observations that we are really proof to its attacks, or if Europeans in India were to become vegetarians they would escape it.

I am sorry to say that I am not in a position to prove my assertion with a list of *post-mortem* examinations, which would certainly be conclusive, but every one of us know how difficult it is to make the people agree to such an examination.

No argument is required to prove that the pathogenic causes for the creation of this fever are amply present in India, where house sanitation is in the most primitive state, latrines not being kept as clean as they ought to be, thus exposing human excretion to the effects of the heat of a tropical sun, where drainage is mostly imperfect, thus making the liquid portion stagnate and putrefy, where heaps of filth are allowed to remain in streets, in the neighbourhood of human dwellings for hours, and in many places for days and months, where the majority of the population are not enlightened enough to look to the purity of their milk and water supply, and where the atmospheric conditions are very favorable for the active multiplication of bacteria, it would be really not only wonderful but miraculous to escape pythogenic fever. There are many who entertain not the least doubt about its existence and free prevalence in India, and a little more careful observation on the part of those who do not as yet believe in it will convince them of its existence in this country, especially in the large cities in an endemic state, the number of cases increasing and decreasing with the change of seasons.

The period of its greatest acting is that of the dry, hot summer months, when filth scattered in fields, collected in heaps near and in villages and towns and lanes saturated with liquid animal excreta, are freely exposed to the hot rays of the sun, and the atmosphere is thus adulterated with gases resulting from the decomposition, with no natural cleaning process except the occasional dust-storms to purify it; next to it the dry part of winter, when the excreta are similarly exposed, but putrefaction does not take place so actively on account of the lowness of temperature; then the rainy season, when a great deal of filth is washed away or soaked into the ground, where it is largely disinfected by the natural disinfectant, the earth, when malaria takes its place or complicates it, but typical cases are sometimes seen at this time of the year also; and last of all the spring, when, in addition to the lowness of temperature retarding decomposition, the gases arising from the surface of the land are absorbed by the free growth of vegetation in every variety and form.

* Read at the Indian Medical Congress, and sent to the Record for publication.

and corresponds in some measure with that of Davos Platz. Phthisis is unknown in Ladak.

The people are very dirty in their persons, and the men wear the Chinese pig-tail, composed of natural hair *plus* additions of string, rags, &c., until of the "regulation" length. This tail dangles on the back and leaves a dirty black, greasy streak on the garment underneath. Beneath this again the Ladaki wears his clean or "best" suit. The women are all polyandrist—this fact, together with the *bona fide* celibacy of the Lama priests, maintains an even balance between over-population and the production of the province.

As we have seen, the climate of Leh is bracing and healthy. Hence the epidemic of small-pox which broke out in the autumn of 1892, during my tenure of office in Leh as medical missionary, came upon the inhabitants with appalling astonishment. An epidemic of short duration *had* been known to have occurred *once*, in the history of Leh, 15 years previously, but small-pox was thought to have been stamped out. The exciting cause of the present outbreak was, no doubt, in some measure due to the influx of Kashmiris, just getting over the disease, having either caught it *en route* to Leh, or started from Kashmir with the disease on them, and spreading it by means of loose scales from the scabs. Every third man one meets in Kashmir is small-pox pitted, as during an epidemic they take no precautions to segregate, simply leaving the disease to run its own course, meanwhile the wretched patient stoically resigns himself to all consequences, once he finds the disease is on him, taking not the *slightest* care to use general remedies, or to ameliorate and render more comfortable the sick bed. "Die or live, let nature take its course" is his motto.

This influx into Leh is usually during the months of July, August and September (when the passes are open and admit of travelling) when it becomes, for the time being, quite a busy, noisy little town, and the rendezvous of natives from all parts of Ladak, Lhasa, other parts of Tibet, China, Kashgar, Yarkand, Kashmir and India, for the sale and purchase of their respective wares, such as rich silk, tea, precious stones, skins, dried apricot, "charras" (a kind of intoxicant) &c.

The Lamas are the spiritual, medical, and temporal advisers of the lay people, who vest in them the charge of their souls and bodies, expecting the priests to do all that is necessary for them, in order to enter *Nirvana* hereafter, e.g., write out prayers for their prayer-wheels, waft prayers to heaven on their behalf, &c.

The onus lies on them to feed and maintain the Lama priests, some of whom are thus exceedingly well off.

The method of vaccination used by the Lamas should more accurately be termed—*inoculation*.

Their method of procedure, based on the erroneous supposition that one attack of small-pox immunises a patient against a second and subsequent attacks, is as follows:—A quantity of virus is procured from a number of ripe small-pox pustules (about 8 days' old) which is all collected and diluted with water in a small earthenware vessel. This is now ready for use. The instrument used is one made of four long needles tied firmly together with their pointed ends on a level. This is dipped into the virus, and then rapidly and deeply *prodded* into the skin and muscle between

the thumb and forefinger on the dorsum of one hand only—usually the left. As there are generally some thousands to be inoculated, the operation, in many instances, is done very imperfectly, and owing to the rapidity with which it is performed, a very small quantity of virus enters a very superficially made wound, and the poor unfortunate either escapes the *inoculation* "outbreak" altogether or has a very slight one, only to be carried off with a most virulent attack during an epidemic, his fond hopes of immunity all crushed, shattered and scattered to the winds. This inoculation brings out an attack of variola, which is very mild (owing to the extreme dilution of the virus, *purposely* done in order to bring out only a mild eruption) and runs a very irregular course. The patient is well in a few days and imagines that he is now "proof" against any further attacks. An epidemic soon tests this fragile protective fabrication in a most thorough, searching and penetrating manner, and finding in it no barrier, no protection against itself, with a ready entrance, soon lays its subject low with the ground.

During the outbreak of 1892, I was waited upon by a deputation of Lama priests to give them permission to hold a public "vaccination" (after *their* method) in my hospital compound, whilst I, the doctor, was to stand aside and behold the quackish farce, seeing all my teachings in the art of vaccination set aside and contemptuously ignored. I, of course, resolutely refused their request, and in addition had my Lama friends prohibited by law, (through the kind help of the British Joint-Commissioner, Ladak and the Dewan of Lep) from carrying on their nefarious practice in public. At the same time I announced it publicly that I would perform a *different* kind of vaccination upon such as cared to undergo the operation.

On application to the Residency Surgeon, Kashmir, I received 19 tubes of lymph, which were all forthwith used up in vaccinating cases. The results were watched with very great scepticism, suspicion, and curiosity on all sides. We were all doomed to disappointment, and I, in particular, to ridicule by the Lama priests, for *not a single* vesicle rose, the lymph sent was inert *in toto*, and the whole thing seemed like "playing at vaccination." When the Lamas compared their *tangible* results with my *negative* results, they wisely shook their heads and condemned the new vaccination summarily. This was, of course, only what could be expected under the circumstances. I felt defeated for once, for failure just at the threshold of the introduction of a new method and system of vaccination in a strange country, where superstitious notions prevail concerning it, was of all things, most undesirable.

I, however, communicated these facts to the Residency Surgeon, and wrote for a supply of fresh lymph. This time I received 32 tubes, and was ready again for vaccination. *But*—would any one venture after such a miserable exhibition of failure? Would any have faith in me and my vaccination to trust themselves to a second experiment? &c., were questions that vexed me the whole of the first night after reception of my second supply of lymph. The next morning my hospital assistant, the caretaker of the hospital, and many of the Christian community came forward to be vaccinated, as also some out-patients at the dispensary. The operation was a grand success *this* time, and was praised by all, especially in that no general eruption broke out over the body and face, as is the case after a Lama "vaccination."

After all the lymph from the tubes was utilised, we carried on vaccination from arm to arm. Thus the fame of the "new vaccination" took deep root in Leh itself, and rapidly spread among the outlying villages. Delegates were sent to us daily, praying us to visit their respective villages and perform the "new vaccination." These solicitations we acceded to as far as we could, and as soon as we had leisure at head-quarters, we set out itinerating first among the neighbouring villages, and afterwards among further outlying ones, until in all upwards of 2,000 cases of *successful* vaccination were recorded.

During the epidemic, I had a house placed at my disposal for a hospital, but many patients preferred living in tents put up in rude Ladaki fashion. With every precaution used, it was very difficult to segregate the patients. It was painful to see case after case come in, previously "vaccinated" by a Lama, the present attack not in the least modified by the "vaccination." Some came in with the disease on them for the second and third time. On the other hand, there were two or three cases that had been *genuinely* vaccinated in the arm by some surgeon, years previously; in these it was most interesting to notice the very *modified* nature of the variola. Only about a dozen vesicles, about the face and body, which lasted but a few days, the patient convalesced rapidly, and was well in a very short time. Comparing these cases with those "vaccinated" by the Lama method, a lamentable mortality attended the latter, while in *every instance* the former escaped with but a very modified attack.

Such were the nature and general features of the epidemic of 1892, which began in August and lingered on till very near November, solely because it was impossible to segregate the cases, especially those occurring among the "purdah" women and their families. The mortality was very high, being fully 50 per cent.

THE NECESSITY FOR AN ACT RESTRICTING THE FREE SALE OF POISONS IN BENGAL *

BY SURGEON-MAJOR J. F. EVANS, M.B.,
and

ASSISTANT SURGEON CHUN LAL BOSE, M.B., F.R.S.
Chemical Examiners to the Government of Bengal.

(Continued from page 134, Vol. VIII.)

B. NATURE OF THE CASES OF POISONING.

It will be observed as the description of the nature of these cases proceeds, that the users of poisons are very conservative in their application. Each poison has, as it were, its own rôle or specific use, and is comparatively but seldom employed for other purposes. Thus arsenic is the poison usually selected for murder and cattle destruction, opium is the poison with which to effect suicide, *datura* the drug with which to produce stupefaction and thus facilitate theft, and so on.

The poison selected is generally that which by long established precedent has become the recognised means for effecting the desired purpose.

The import or production of some of these poisons is already under the control of the authorities; in the case of

some of the others, however, which grow wild or nearly so, any effectual control will be difficult.

From what has already been said, an account of the nature of poisoning cases resolves itself into a description of the classes of poisoning which occur, with the poisons which are generally used in each class.

The cases can conveniently be arranged into the following seven classes:—

I. Murder by poison.

H. Administration of stupefying drugs in order to facilitate theft.

III. Administration of poison to effect destruction of the intellect.

IV. Administration of poison to effect abortion.

V. Cattle poisoning.

VI. Suicide by poison.

VII. Accidental poisoning.

Each class will be dealt with in turn, with special reference to the poison most frequently used in each class. A few fairly illustrative cases will also be cited by way of demonstrating the methods of administration.

I. MURDER BY POISON.

Crime of this kind is rare in England; and the facilities for detection and difficulties of concealment are such that the statistics may be regarded as highly reliable. It is hardly possible to assume the same confidence with regard to the available returns in Bengal, for not only are the facilities for detection less but the possibilities of concealment much greater. In India the symptoms of natural disease and the effects produced by poison simulate each other to an extent quite unknown in England, occasionally baffling even experienced medical men. The fact that notwithstanding difficulties of detection *murder by poison* is three times more prevalent in Bengal than in England sufficiently indicates an unsatisfactory state of affairs. The circumstances attending specific instances of poisoning illustrate this more fully.

In England it is almost impossible for an individual during a sudden fit of passion to be able to obtain and administer poison to those with whose conduct he or she is incensed. For unless the circumstances were special, such an individual could only procure sufficient poison for his or her purpose after the lapse of a period of time sufficient probably for reason to have regained control of anger.

Such cases however do occur in India. We can adduce instances, the occurrence of which can only be attributed to the ease and rapidity with which the poison was procured.

Thus in 1893 the youngest brother in a high caste Brahmin family, residing in the vicinity of Calcutta, having had some misunderstanding with two of his elder brothers quietly entered the kitchen and mixed powdered white arsenic with some common salt lying there for immediate use. A curry was prepared with the poisoned salt and eaten by several members of the family, all of whom developed symptoms of irritant poisoning. Fortunately the quantity of salt used was small and but little of the curry was partaken at the particular meal. The victims all recovered. The common salt, the curry, and the vomit of some of the affected persons were sent for examination. Arsenic was detected in all of them. The culprit is still at large.

* Being a paper read at the Indian Medical Congress and sent to the Record for publication.

Such cases can be multiplied, but the example given is a typical one of its kind. Typical too in many ways, in the absence of premeditation, the method of administration and the selection of the poison. The two poisons most readily attainable are probably opium and arsenic. The former is not suited to the murderer's purpose, for its appearance and taste might lead to its early discovery. White arsenic, on the other hand, is tasteless and powdered and mixed with common salt would readily escape detection.

Motives for murder.—Classified according to the motive, cases of murder by poison in India can easily be arranged into types equally familiar in all countries. Thus in India as in other countries revenge, jealousy, lust, greed and avarice may any one of them instigate the act. The motives are the same everywhere. Have they borne more fruit in India, and if so, why?

The poisoner's art is probably older in India than among the modern nations of Europe; and it may be argued that use has begotten use till familiarity with the nature and effects of poisonous drugs has become very general. It is much to be doubted whether at any time in England uneducated people possessed the acquaintance with poisons which belongs to certain classes among the poor and uneducated masses in India to-day. Such poisons as they knew, and knew well, were fortunately less potent.

We do not mean to suggest that the criminal class is proportionately larger in India than in England; for we believe that it is not; but it would appear that a sense of the value of human life has taken a stronger hold of the masses in England than in India. The smaller appreciation of the value of human life in India may possibly have originated to a certain extent in her religious teaching, which tends to exalt the value of a future existence at the expense of the estimation in which, present, temporal and material possessions and even life itself, should be held. Then her teeming population and the struggle for existence with the thin margin which separates many millions from difficulty or want may serve to have accentuated a tendency which, while harmless on the part of non-criminal minds, becomes dangerous among the criminal classes.

The feeling regarding human life which exists in England to-day did not always exist. It has taken many years to develop. Time and the spread of education will, it may be hoped, engender a similar sense among the masses in India.

We have referred to those acts of poison administration which resemble acts of homicidal violence during the heat of passion, and which probably are often followed by as speedy a repentance.

But besides cases of this kind, a very large number occur annually where the poison has been administered after long premeditation and with deliberate intent. Our paper is intended to demonstrate the need for legislative interference with the free sale of poisons in India and for the enactment of laws regarding the possession of poisons by individuals in this country similar to those in England.

If such measures are to be successfully introduced, cognizance must be taken of all the circumstances special to India. It would naturally be supposed that cases of deliberate poisoning premeditated during a considerable period

of time, are those which can be dealt with least effectively and with the greatest difficulty. The poisoner has time, and may be opportunity, to select a poison, the detection of which is difficult. Does he do so?

Selection of poison.—Experience shows that he seldom attempts anything of the kind, but utilizes the one well-known poison, viz., arsenic. Scientific poisoning is practically unknown in India. As a rule, large quantities of poison are administered, and whether the act be sudden or long premeditated, the one poison commonly chosen to effect murder is the easily detected poison, *arsenic*.

We will cite a case of long premeditated and determined murder by poison which occurred in 1893, to illustrate the point:

A Sikh named RAJAH SINGH, the prospective heir to some property, had a long-standing dispute with some of his co-religionists regarding the estate. Taken one day by one of these men, JOWHAR SINGH, to the Sikh temple in Burrabazar, he was given "*Karaprasad*" a sweet-meat sacred among the Sikhs to eat. While eating it, RAJAH SINGH objected to the taste, and protesting that it was not the real "*Karaprasad*" but ordinary sweet-meat or "*halwa*" wanted to eject it from his mouth. He was however persuaded to swallow the sweet-meat on the ground that as a true Sikh he ought not to insult the "*Karaprasad*."

Shortly after he left the temple to return to his house, but became ill on the road and vomited once. On arriving at his house, he became very ill, suffering from vomiting and purging.

Suspecting that he had been poisoned, he communicated his suspicions to his mother and other relatives. He was then taken to the Medical College Hospital, where his stomach was washed out and where he made the above statement to the medical officer on duty. Next day he died. The stomach washings and viscera were sent to the Chemical Examiner for analysis, and arsenic detected in both of them.

Here avarice was the motive. Very frequently the motive is lust. Thus during 1881, a case was referred from Cooh Behar in which a faithless wife poisoned her husband with arsenic and afterwards married her paramour.

Arsenic has occasionally been used by step-mothers to remove unsatisfactory step-sons. In May 1884, CHARCOO NASTA, a Mahomedan lad aged 19 years, died at Diuagapore with symptoms of vomiting and purging after partaking of food given him by his step-mother. Arsenic was detected in the vomited matters, and also in the viscera.

In cases of murder by poison, white arsenic is chiefly used, yellow arsenic occasionally, and red arsenic rarely. *Darmoj* and other arsenical preparations are very rarely employed.

As will be shown later on, the greater quantity of arsenic in the country has been imported by sea. The quantity naturally available in India is very small; yet to-day the drug is to be found every where. How then has its dissemination and the knowledge of its properties become so general?

The question is interesting and not entirely speculative; for it might be possible from such data to ascertain the period of its rise into favor as a poison.

We have stated that arsenic is the poison most frequently used to effect murder. A definite statement giving the

percentage of cases of murder by poison in which arsenic has been the poison selected ought to be forthcoming. Unfortunately no such statement is available.

The Chemical Examiner's reports shew in what proportion of fatal cases of poisoning of all kinds arsenic has been detected, but the cases cannot be classified with any certainty by the Chemical Examiner from the information supplied to him.

Next in frequency of use to arsenic comes *aconite*. The following is a typical case of *aconite* poisoning. On 6th May 1891, 3 coolies of the Chamar caste were found lying dead in the Dhurmutolah market; 2 others were unconscious, but subsequently recovered. The investigation shewed that all five men had been poisoned with *aconite* mixed in their food by one JETROO Chamar at the instigation of SHUNNOO Chamar. All concerned were fellow countrymen, and had been friends up to the time of the act, the cause for which apparently consisted in the fact that one of the murdered men had a quarrel with JETROO Chamar, who thereupon introduced poison into the common meal of five individuals with four of whom he was not in any way at variance.

No example could be more striking of the recklessness of the poisoner on the one hand or on the other of the small provocation required in some instances to induce the act.

Besides *arsenic* and *aconite*, preparations of *mercury*, *copper*, *antimony* and *nuxvomica* are occasionally, though rarely, used for the purpose of murder.

The small and other physical characters of opium are effectual obstacles to its frequent employment for murder. It is used however to effect infanticide, and sometimes is given in wine to drunken individuals to effect murder.

On one or two occasions of late years, the alkaloids *strychnine* and *morphine* have been employed.

The method of administration is that in use from time immemorial, *viz.*, of mixing the poison with the food. Thus yellow arsenic can be fairly well concealed in dal, curry, and white arsenic in common salt. All articles of food are utilised. If the poison be tasteless or nearly so, and well concealed in the food, the better is it taken by the victim.

II. ADMINISTERING OF STUPEFYING DRUGS TO FACILITATE THEFT.

This class of crime is but little known in Europe. In India it is very frequent. The police returns for the province of Bengal show that 23 cases of administration of stupefying drugs to cause lurt occurred in 1893.

The drug almost universally employed is *datura*, well known as the *thug* poison, since those of the *thug* gangs who were not adepts in the use of the sling, employed *datura* to drug their victims and subsequently robbed them when helpless.

The history of one instance of *datura* poisoning is practically the history of all of them. A stranger joins a party of individuals on a journey, and wins their confidence sufficiently to be allowed to cook or prepare their food into which he introduces powdered *datura* seeds. On one plea or another he excuses himself from partaking of the common meal which is eaten by the remainder of the party, who succumb to the influence of the drug and are easily robbed.

Robbery by means of *datura* is almost a profession, and many of those who practise it display considerable dexterity in the method by means of which the admixture of the poison with the food of their victims is carried out. The use of a hollow pestle filled with powdered *datura* seeds and having a small orifice at the lower end is sometimes resorted to. The pestle is employed to grind the pepper and other condiments for use in cooking the food, and the drug is thus successfully introduced therein without even exciting the suspicion of the victims.

The employment of *datura* is probably encouraged by the popular belief that it produces unconsciousness only and not a fatal result. The use is for the purpose of making robbery easy and of avoiding violence. Murder is not the object but the reverse. The administration frequently, however, results in murder, as the following record will show:—

In July of this year (1894) at Monghyr, *datura* was administered to the crew of a boat numbering 8 persons, one of whom subsequently died from the effects of the drug. The robbers got off with their booty. As the case is typical, the following account furnished by Surgeon Major D. G. CRAWFORD may prove interesting:—

"Two men took a boat at Sompur to carry them to Naraingarj. On the evening of the 22nd July the boat was tied up for the night at Gogri, opposite Monghyr. The crew consisting of seven men and a boy (son of deceased) took their food as usual about 9 or 10 p. m. They went to sleep. Next morning they were all found insensible and one died about noon. The other seven were sent to Monghyr where they arrived at about 2 p. m. to-day (24th July). I saw them at about 4 p. m. All had somewhat dilated pupils. One talked somewhat incoherently, the rest appeared to have fully recovered. All their property had disappeared: so had the two passengers who are supposed to have mixed drugs in their food for purpose of robbery. The two passengers being of a different caste did not eat with the crew."

In most cases of *datura* poisoning, the whole fruit or powdered seed is administered mixed with solid food. In such cases, fragments of the seed can frequently be detected on microscopic examination in the vomited matters, the excrement and in the food. Occasionally, though not frequently, spirituous liquors are made the vehicle for the administration of the drug. During the current year a case occurred in which *datura* was administered in this manner. A prostitute was visited by a man who, in the course of the interview, offered the woman some country liquor to drink, and in proof of its character drank some himself. After drinking the liquor the woman became unconscious and the man, with whom she had had no previous acquaintance, having stripped her of her ornaments tried to decamp. In this case *daturine* was extracted from the country liquor, from the stomach washings and from the excrement of the poisoned woman, as well as from the stomach washings of the accused.

Administration of datura to facilitate murder by violence.—As already stated, the employment of *datura* is almost invariably for the purpose of facilitating theft. One instance however occurred during the current year (1894) where it was administered to facilitate the murder by violence of a Hindu male, sixty-five years of age.

This man had two wives, of whom the younger MATANGINI, had contracted an intimacy with another man. The husband objected to his wife's misconduct, in which, however, she persisted, notwithstanding an occasional beating at the hands of her husband. On 30th May, instigated by the woman who arranged the interviews with her paramour, MATANGINI mixed a whole *datura* fruit in the curry which formed her husband's meal. When the husband had become unconscious, MATANGINI killed him with a *dao*. On the discovery of the dead body, the murderess made a full confession of her crime.

III. ADMINISTRATION OF POISON TO EFFECT DESTRUCTION OF THE INTELLECT.

Such cases of the crime as might come to the notice of the authorities would no doubt be included under the heading of the administration of stupefying drugs to cause hurt. The drug employed is almost always *datura*. But little is known regarding the crime and the production of specific instances is impossible. It is carried out secretly and very gradually, so as to simulate the natural course of mental disease and to excite the suspicion neither of the victim nor his friends. It is stated that women administer *datura* to their husbands in this manner, in order to obtain opportunity for the successful prosecution of love intrigues; and that prospective heirs to large properties are thus deprived of reason by individuals interested in the succession, as under Hindu law insanity is a bar to inheritance.

IV. ADMINISTRATION OF POISON TO PROCURE ABORTION.

Unsatisfactory statistics of abortion cases.—The average annual number of cases of abortion reported in the Bengal Police Administration Return for the years 1888 to 1892 was 24. It is not stated whether these are cases of simple abortion or death, the result of the attempt. In none of these years either was any case reported as having occurred in the town of Calcutta.

The small number of the cases reported for the whole of the province, and the fact that none are reported from the town of Calcutta, may be taken as almost sufficient evidence that a small number only of the cases that actually occur ever come to light.

A practice in procuring abortion is carried on by certain women of low caste, who occasionally administer sufficient poison to their clients to effect a double murder. These women frequently pass themselves off as midwives.

Methods employed to effect criminal abortion.—The method generally employed is the introduction into the cervix uteri of the stems or roots of plants which possess irritant active principles. Thus *Plumbago Rosea* (*Lalchitra*), *Nerium Odorum* (*Karabi*), *Calotropis Gigantea* (*aband*), *Euphorbia Tirucalli* (*Lankasij*) and others are utilised. Sometimes bamboo sticks coated with assafoetida are introduced to effect the purpose.

The violence used together with the local action of the drug occasionally sets up hæmorrhage or septicæmia, ending in a fatal issue and the discovery of the crime.

Now and then drugs are internally administered in the attempt to procure abortion, and have been found after death in the viscera of women who have died as the result of the attempt. Arsenic, yellow oleander, *Colocynthis*, *plumbagin* (the active principle of *lalchitra*) and other poisons have been detected in the viscera in such cases.

V. SUICIDAL POISONING.

Serious increase of suicide by poison.—The degree to which suicide prevails throughout the province of Bengal has already been dealt with. It has been pointed out that there is every reason to believe that suicide is on the increase, at any rate in Calcutta and other large towns. Part of this apparent increase may be due to the better system of records now in vogue in Calcutta; but it can hardly account for the total increase which the figures indicate. Thus the total suicides from all causes in Calcutta town and suburbs, which were 84.94 per million per annum for the five years 1876 to 1880 had swollen to 123.52 per million per annum during the five years 1889 to 1893, shewing an increase of 38.58 per million. This fact is serious, and becomes more so, when it is understood that of the total increase of 38.58 per million, suicide by poison accounted for 32.42 per million.

Selection of poison.—Of the total suicides occurring annually in the town and suburbs of Calcutta, 40 per cent. are accomplished by taking opium, arsenic is selected in 5 per cent. of the cases, and other poisons not indicated in 11 per cent.

Among the population dwelling in the municipal area of Calcutta during the year 1st June 1893 to 1st June 1894, 52 deaths by poison occurred; of these 44 (all suicidal) were due to opium or 84.6 per cent.*

The facts then that claim attention are the following, viz.—

(a). That the crime of self-destruction has enormously increased during the last ten years, and that the cases which have produced the increase are almost entirely those of suicide by poison: for while during the five years 1876 to 1880 the average of suicide by poison to the population was 36.42 per million, in the period 1889 to 1893 it had risen to 68.84 per million or nearly double.†

(b). Of 100 cases of suicide occurring in the town and suburbs of Calcutta, 56 are due to poison; and of the 56, in 40 opium has been the poison taken, in 5 arsenic, and in 11 other poisons.

It is well recognised by the writers of this paper that the conditions of life existing in the town of Calcutta find no counterpart in the rural districts of the province, and only to a limited extent in the large towns at the present time. Still as increase in the crime may be regarded as the outcome of unhealthy social conditions, and as the social conditions existing in Calcutta must sooner or later prevail in all the towns of the province, and at some remote period in the rural districts also, it would be interesting to enquire what those social conditions are, in which an explanation of the increase in the crime of suicide must be sought.

* Dr. J. B. Gibbons informs us that of the 52 cases of poisoning in which he made a post-mortem examination 44 were due to opium, 1 to sulphuric acid, 5 to arsenic and 2 to hydrocyanic acid.

† Suicides from all causes in the town and suburbs of Calcutta:—

| | | per million |
|-------------------------------------------------------|----------|-------------|
| During the period 1876-1880 | | 84.94 |
| Ditto 1889-1893 | | 123.52 |
| | increase | 38.58 |
| Suicide by means of poison throughout the same area:— | | |
| During the period 1876-1880 | | 36.42 |
| Ditto 1889-1893 | | 68.84 |
| | increase | 32.42 |

Social conditions contributing to the increase in the occurrence of suicide.—Except in a certain proportion of those cases where suicide is resorted to in order to escape the extreme penalty of the law, it is justifiable to regard all cases of self-destruction as the result of a temporarily or permanently unsound mental state. A healthy mind in a healthy body is probably the greatest of earthly blessings. Their varying conditions mutually interact however to the impairment or otherwise of their individual functions. Thus the physical conditions of the dwellers in large towns are often such as to interfere with healthy mental action and development.

A disease or unsound state of mind may be permanent or temporary, may arise from the exaggerated development of certain mental attributes or from a deficiency in the development of others. It may be organic lesion or functional derangement only, and may proceed from over-strain, from vicious habits of life, or from over-indulgence as the addiction to the excessive use of alcohol or Indian hemp and other drugs.

In a large population there is always a certain proportion of mentally weak individuals in whom the condition either exists as a congenital defect, or has become developed as the temporary or permanent result of circumstances. In the case of such individuals, self-control is weak or deficient, and imagination not habitually kept in check by the higher mental faculties.

When a community is affected by any social wave or change, these are the members of the community who, as a rule, display the most evident symptoms of the movement, acting as it were the part of social weather-cocks. They are the most ready to adopt new phases of thought and to sever themselves from their ancient religion and traditions. The religious system of a country is for the most part calculated to support its social fabric, to assist the individual in maintaining moral and mental self-control not only in times of prosperity, but also in times of adversity.

It may be noted in the histories of nations, that when the influence of the national religion is weakened from any cause, a measure of social convulsion often ensues. The extent and nature of the social movement must depend upon the natural mental calibre of the country, if outside influence be excluded. At the present time in Calcutta and other large towns of India, a social movement of the kind referred to is taking place chiefly among the younger members of the community, who seem to be emancipating themselves from the tradition and influence of their ancient religion. Those among them less mentally robust than the majority are thus deprived not only of that support which religious belief affords to weak wills, but also of the influence which the doctrines of their religion exert. Thus as regards suicide, the *shastras* inculcate that there is no salvation for the individual who has destroyed his own life. In former times, the Hindu placed implicit faith in the *shastras*, but his descendants are in many instances falling away from the belief.

The modern Hindu is more an artificial than a natural product. Furnished even in his own country with a foreign education and living within touch of a foreign system of civilisation, he has in many cases lost the patience

and resignation engendered by his ancient creed to gain instead imaginary wants and wild aspirations improbable of realisation. Such influences acting upon any mind not absolutely sound are prone to produce outbursts of one kind or another on small provocation. A hypersensitive condition is induced and events quite insufficient by themselves upset a feeble mental balance and give rise to such an exaggerated estimate of even trifling troubles that self destruction is resorted to.

Exciting causes inducing suicide.—The exciting causes which acting on an unhealthy mind induce suicide are the same in every country.

Ill-treatment, quarrels, jealousy, despair, destitution and physical suffering, all can claim their victims, and among both sexes. But in Bengal, as in England, the incidence of suicide is unequal in the two sexes. In England the male sex furnishes the larger number of cases, in Bengal the female, according to the Sanitary Commissioner's Reports.

It has been shewn that suicide has increased of late to a painful extent among the Hindu population of Calcutta. The cases that occur are of all kinds. Thus merchants on pecuniary reverse, students failing to pass their examinations, disappointed suitors, wayward sons checked by their parents and unhappy girl-wives, all attempt to find in suicide an escape from their real or supposed misfortunes.

The minds of the young, possibly the women chiefly, do not acquire a healthy tone from the perusal of the sensational worthless novels now being published in large numbers by the vernacular press of Bengal.

We presume that every one now-a-days admits that persons who attempt or commit suicide should in most instances be regarded as either permanently or temporarily irresponsible for their actions. They are therefore legitimate objects of care to the legislator according to the modern conception of civilisation; and since the easy accessibility of poison is responsible for a large number of suicides, it is this very easy accessibility of poison which should first be dealt with by legislative interference.

Opium has been shewn to be responsible for the majority of cases of suicide in the municipal area of Calcutta whether by violence or otherwise; and opium is to be found in any quantity everywhere throughout the country. Other poisons are also used, and among them some the introduction of which into the country is only of recent date, and due to the development of certain trades such as photography and electro-gilding. By this means *cyanide of potassium* has become known and has been employed in one or two cases. The extensive development in the trade of European drugs has familiarised many among the educated classes with their qualities and led to their employment also to effect suicide.

No definite statistics as to frequency of use of the different poisons for suicide throughout the province.—As already stated, no figures are available to shew what proportion of the suicides reported in the Sanitary Commissioner's Return is due to poisoning, or what was the nature of the poisons chiefly selected. It is accordingly very difficult to obtain any idea not only as to the number, but also as to the nature of cases of suicide by poison occurring in the province outside Calcutta.

of a large number of cysts and daughter-cysts measuring 40 fluid ounces, thus making a total of 203 fluid ounces. The cavity was thoroughly irrigated with a solution of the bichloride of mercury 1—2000, dried as well as possible and dusted internally with iodoform. The sac wall was now sutured to the external wound by means of silk worm gut. A large sized drainage tube inserted into the cavity (13 inches in length and 1 inch in diameter), the whole being covered over with absorbent salicylic wool and bandaged.

Symptoms, 16th April.—Patient restless and faint; temperature 7 a.m. 100.2° F., 7 a.m. normal; wound irrigated and dressed antiseptically; percussion gives a resonant note all over right side of chest; no breath sounds are audible on auscultation.

19th April.—Patient continues very restless. Evening temperature ranges from 100.4° to 102° F. Morning temperature ranges from 98° to 99.6° F. Breathing short and hurried; no pain; wound healthily looking; discharge scanty but sweet; cavity irrigated and dressed twice a day; micturates frequently; bowels constipated.

21st April.—Had a fair night's rest; breathing still hurried and somewhat difficult; no pain; the discharge is now slightly more profuse; a few sloughs (hydatid membrane) and daughter cysts escaping during irrigation; matters removed; wound healthy; takes nourishment well; complains of great thirst; bowels moved after a laxative.

23rd April.—Has been very restless; extremities cold and clammy; is losing flesh rapidly; temperature ranges between 101° and 102.8° F.; respiration hurried; pulse very weak and rapid; discharge now very profuse and offensive; the whole cavity suppurating freely; cavity irrigated twice daily and dressed; diarrhoea has unfortunately set in, he having had 9 stools in 11 hours of a yellowish, loose and highly offensive character.

26th April.—Nights have been very restless; sleeping only in snatches; is bathed in perspiration; extremities clammy; temperature ranges between 100° and 103° F.; discharge very profuse and offensive; diarrhoea continues to exhaust him.

30th April.—Patient very restless but perfectly conscious; extremities are cold and clammy; temperature ranges between 102° or 103.8° F.; pulse weak, 146 per minute; respiration hurried; breathing stertorous; discharge extremely profuse and offensive; diarrhoea severe, 12 to 14 stools in 24 hours. He continues to take his nourishments extremely well.

1st May.—Died at 11 a.m.

Treatment.—Cavity irrigated with the following solutions according as the circumstances arose:—Permanganate of potash gr. $\frac{1}{4}$ to $\frac{3}{4}$; bichloride of mercury 1—2000; tincture of iodine $\text{m} \times \frac{1}{10}$ to $\frac{3}{4}$; zinc sulph. grs. ii to $\frac{3}{4}$; and zinc sulpho carbolat grs. iv to $\frac{3}{4}$.

Internally.—A mixture of quinine sulph., ammon. carb. and decoction of cinchona, Calcis Sulph. gr. i in pill three times a day. Calcis phosphor gr. i in each feed; morphia, bromidia, sulphonal, tincture chloroformæ et morphinæ co; pil plumbi c. opii, vin ipecac, enemata of starch et opii, bismuth et opii, etc.—

Diet.—Beef tea, chicken broth, raw beef juice; calves feet jelly; Mellin's food.

Stimulant.—Brandy and stout.

A post-mortem examination was made, and the whole of the right thoracic cavity was found empty; the pus-discharging surface being very large. The right lung was found collapsed, about the size of a man's fist, but intact showing no communication with the cyst in the right pleural cavity, and lying adherent and adjacent to the left lung on the left of the spinal column on the upper and convex surface of the liver; there was situated a single small hydatid cyst, about the size of a hen's egg, the sac-wall of which was of a yellowish brown color, this apparently had no connection whatsoever with the one arising from the pleura; no perforation of the diaphragm was noticed.

Remarks.—(1) Previously diagnosed as bronchitis; (2) the short duration of symptoms; (3) hydatids of pleura rare; (4) enormous size of cyst; (5) no expansion of lung after operation and no falling back of heart into its proper position. Liver still remained pushed down in the abdominal cavity; (6) adhesions preventing collapse of the walls of the cavity and thereby tending to profuse suppuration, exhaustion and death.

—:—

A CASE OF STRICTURE OF URETHRA; COCK'S OPERATION: RECOVERY.

By F. S. GHANDHY, L.M.S.

Assistant Surgeon, Ranchorelal Dispensary, Ahmedabad.

On the 5th January 1895, at midnight, I was called to see a patient, about 50 years of age, who was suffering from retention of urine. He had suffered from gonorrhoea in his youth.

He had seen me two months before for difficulty in passing urine, when a stricture was detected and he was advised to stay in the hospital; but he would not.

During the day (5th January) he was treated by two other practitioners, who were unable to draw off the urine by a catheter.

When I saw him the bladder was distended and the patient was in great distress. Some blood was oozing out of the urethra, probably the result of previous cathetrization. I tried to pass a catheter, but failed.

I then aspirated the bladder above the pubis and drew off 15 oz. of urine which was mixed with blood. I was not able to empty the bladder, as the bloody urine choked up the trocar of the aspirator.

On the 6th January I was sent for again and found the bladder distended. Aspiration was again tried, but it failed on account of the trocar getting choked up with clots.

At 2 p.m. Cock's operation was performed under chloroform, and a large quantity of dark colored bloody urine was evacuated.

A female catheter was held *in situ* in the artificial opening, and the wound dusted with iodoform and boric acid, and dry lint dressing applied.

7th January.—Temperature 98.4°; patient feels much relieved, clear urine flows out of the catheter.

14th January.—Patient feels very inconvenient on account of the catheter in the perineal wound; catheter removed.

15th January.—Urine passes freely from the meatus urinarius. On trying to pass a catheter through the perineal opening I found it blocked up.

16th January.—Passes urine freely by the urethra. A No. 8 metallic catheter can now be easily passed.

20th January.—The perineal wound has healed up.

Remarks.—This case is remarkable in that aspiration of the bladder was found impracticable on account of the blood in the urine. At one time I thought there was a villous growth in the bladder, but after the escape of all the bloody clots the urine flowed quite clear. It seems therefore that former cathetrizations (probably forcible) had produced bleeding at the seat of stricture from which the blood must have percolated into the bladder.

In a previous case of stricture, where no catheter could be passed, and where there was retention of urine, I aspirated the bladder morning and evening for three days and at last was able to pass a catheter and draw off the urine. The rest given to the stricture relieves it, and allows of subsequent cathetrization which saves the patient from a cutting operation.

Perhaps the same treatment in this case would have been successful, but for the blood clots in the bladder.

However, the operation also gave a very satisfactory result, as the urine began to flow by the natural passage immediately after the removal of the catheter from the wound, and the wound itself healed up very rapidly.

MARCH 1, 1895.

HIS HIGHNESS SIR BHAGVAT SINHJEE,

K.C.I.E., M.B., C.M., M.R.C.P., F.B.U., LL.D., D.C.L.

THAKORE SAHEB OF GONDAL,

Vice-President, Indian Medical Association.

HIS HIGHNESS SIR BHAGVAT SINHJEE, K.C.I.E., M.B., C.M., LL.D., D.C.L., the present Ruler of Gondal—a first class Native State situated very nearly in the exact centre of the historic province of Sanraashtra in Western India—is a Jadeja Rajput by descent, and as such belongs to the lunar dynasty which traces its origin to the renowned KRISHNA. After the great destruction which is said to have befallen this race at Veraval-Patan about 5,300 years ago, the survivors established themselves in Sindh, whence they migrated into Cutch, which country they took possession of by force of arms. After some time a member of their family settled at Hallar in Kathiawar and assumed the name of Jain. The place which he fixed on as his residence is now known by the name of Jain Nagar, the city of Jain. As the members of their family increased, they separated and established independent chiefdoms, such as Gondal, Dhol, Rajkot, &c. The founder of the Gondal House was KUMBHOJI I., who inherited a moiety of his patrimonial estate from his brother SAHEBJI, Chief of Rajkot, and expanded his possessions considerably by his valour and military prowess. The present THAKORE SAHEB is the twelfth in descent from him. At the hands of KUMBHOJI I.'s warlike successors, the taluka had to undergo the process of gradual development till it achieved, as at present, the rank of one of the foremost states in Kathiawar. The resources of the State were vastly increased by several British officers, who were entrusted from time to time with its management during the minority of THAKORE SAHEB BHAGVAT SINHJEE.

The minor Chief was born on the 24th October 1865, and so he was only four years old, when his father SAGRAMJI, of pious memory, died in Bombay. In his boyhood he gave promise of a very hopeful future. Being somewhat modest and reticent in habits, he had more of the thoughtful than the playful boy in him. He was but little fond of frolic, and from the beginning evinced considerable aptitude for study. At the age of nine, the Prince entered the Rajkumar College, an institution then recently established at Rajkot for the education of the Kathiawar aristocracy. His whole college career extending over a period of nine years, was one of uniform success, characterized alike by ability, industry and good behaviour. For a considerable time he maintained the position of head of the college, and without interruption, won the annual prizes either for diligence, drawing, or proficiency in English. He had advanced so far beyond his fellow students that in the words of the principal, "he had to be put in a class by himself." He is a notable product of English education, and well worthy of such praises as were ever bestowed on a member of Indian royalty by such earnest educationalists as MR. CHESTER MACNAUGHAN, PROFESSOR F. G. SELBY and SIR WILLIAM MUIR.

In order to give a finishing touch to his education, he, with the laudable desire of seeing with his own eyes all that was worth studying in the manners and customs of the English people, ventured to undertake a tour in Europe under the guidance of Major (now Colonel) HAMCOCK. He spent nearly four months in England and Scotland, and then made a short tour on the Continent, visiting Paris, Brussels, Hamburg, Lucerne, and other places in Switzerland, Milan, Venice, Florence, Rome, Naples and Brindisi, returning to India on the 13th of November 1883. He has published the experiences and impressions of his travels in the shape of a regularly kept journal or diary, which is a delightful and interesting record of the scenes which the young Prince went through in the course of a somewhat hurried trip of six months' duration. The book is very favorably noticed by the Indian, English and Continental press as much for its style and literary merits as for the fair and independent observations of its royal author. It is a rare thing in India for a Chief to take to book-writing, and this book does no little credit to the youthful Prince.

Soon after his return from his journey, the Chief was initiated into the public business of his State by being associated in administration with Colonel NUTT. He assumed sole charge of his State on the 25th of August 1884. His installation speech is regarded by his people as a *Magna Charta*, inasmuch as it puts forth an important declaration of his future policy, and it was so very thoughtful and effective, that the Governor in Council publicly complimented him for the matter and tone of it. "Subsequent events have shown," says the *Times of India* of 31st July last, "that the high professions in the speech were real, and that the ends of government which the young Chief then defined have been kept clearly and practically in view."

In the same year he was nominated a Fellow of the Bombay University—an honor to which his literary pursuits fully entitled him. In the early part of 1886, the THAKORE SAHEB again proceeded to Scotland, with a view to reside for some time at the Edinburgh University. He stayed there over fifteen months, and so much distinguished himself as a willing and diligent student of science, that the old Scottish University thought fit to confer on him the honorary degree of LL.D.—a distinction never before bestowed on a native of the Bombay Presidency. He was present in England at the time of the grand Jubilee festivities in the capacity of a member of the deputation sent to that country by all the chiefs of Kathiawar, and was fortunate enough to receive from the hand of Her Majesty in person the insignia of Knight Commander of the most eminent order of the Indian Empire. He returned to India on the 13th of August 1887. The day was a memorable one, as the Thakore Saheb received from his subjects a grand ovation on his safe return home. Addresses of welcome and congratulations were showered on him from all sides, and young and old, rich and poor, all turned out to a man to honor and greet him. The same year the Government of Her Majesty the Queen-Empress was pleased to raise Gondal to the rank of a first class Native State "on account of

its importance and advanced administration," and to announce that in future the Rulers of Gondal would be entitled to a salute of eleven guns—thus affording no small personal satisfaction to His Highness to find his State advance, his *regime* both in rank and power, and recognised as one of the best governed states in India.

In the beginning of the year 1890, His Highness' beloved consort, RANI SHRI NANKUNDEBA of Dharampore was taken suddenly very ill, so much so that her doctors strongly advised her to go on a long sea voyage and reside for a time in England under the best medical treatment available there. Accordingly, His Highness was obliged to set sail on the 21st March, with his Rani and children, leaving his Dewan in charge of the State. This Rajput lady was the first Rani of an Indian ruling Chief who ventured to set aside her caste prejudices and to cross the ocean or the 'Kali-pani' as they call it in India. Her Highness had to be kept under medical treatment for over two years, during which time her health saw much improvement. His Highness the Thakore Sahib, who is studious by nature, could not allow this long interval to press heavily on his head. Being very fond of science, and especially of medical science, of which he is a dilettante—he again joined the Edinburgh University, and with the assiduity of a regular student, qualified himself for the high degrees of M. B. and C. M. in that faculty and earned the diploma of M. R. C. P. in the ordinary course. In June 1892, the distinguished University of Oxford, on the occasion of its commemoration day, thought fit to confer on His Highness the Honorary Degree of D. C. L. His Highness may well be proud of this rare academic distinction, which also seems to have greatly rejoiced his subjects, whose idol he is and who, in appreciation of his just and beneficent rule have, with one accord, voted him a colossal bronze statue by public subscription. This is unique in the history of the province; for one must search in vain for a parallel in which the good deeds of a living Chief are sought to be held in such honorable remembrance by his people.

It is pleasant to note that the object which had induced His Highness to take his Rani to England was accomplished beyond all expectation. Her Highness's health considerably improved under the skilful treatment of the Edinburgh doctors. This was highly gratifying to the people of Gondal, whose gratification was much enhanced when they came to learn that the membership of the Crown of India had been conferred on Her Highness by Her Majesty Queen Victoria.

After having graduated in medicine, His Highness, accompanied by his convalescent Rani, returned to India in the beginning of 1893 *via* America, Japan, China, Australia and Ceylon, thus accomplishing the daring feat of touring round the world. His Highness and his courageous spouse have earned the reputation of being one of the most travelled couples on this side of the world. The dauntless Rajput Princess is the first of her class and rank who has discarded the *purdah*, accompanied her lord to a foreign country, sharing his joys and sorrows, and proceeded in circumnavigating the earth. In response to an invitation, their Highnesses had the pleasure of paying another visit to England on the occasion of the opening ceremony of the Imperial Institute.

The time has not perhaps come of pronouncing a definite judgment upon the career of this enthusiastic young Chief, whose plans and ideas of a sound and enlightened government have not yet possibly been given full scope. Still if what he has already done for his people be taken as an earnest of what is to follow, His Highness may justly lay claim to be called a very capable and efficient administrator. He takes a keen and intelligent interest in his administration, and nothing is done without his knowledge. He regularly attends office at stated hours, and carefully looks to the wants of his subjects. He has created the office of a travelling doctor with a view to afford medical aid to villagers who are living at a distance from the principal towns, where there are dispensaries. The duty of the travelling doctor is to visit the villagers in periodical rounds and give medical assistance on the spot to the ignorant and the poor who cannot conveniently resort to hospitals. This novel experiment has answered so well that in the opinion of LORD HARRIS, His Highness' "example may be copied not only in Native States, but also in British territory." The Gondal Infirmary, known as the Bai Sahib Ba Asylum and Orphanage, is also the first and the best institution of its kind in the province. It is founded in memory of His Highness' deceased wife Bai Sahib Ba. In this Asylum the infirm and disabled, who are unable to earn their livelihood, and are otherwise uncared for and neglected, are provided with clothes, board, lodging and medical aid. Separate wards are assigned to separate castes, and thus the institution is a real blessing to many laboring under physical disabilities. "The success of this unique institution," says SIR CHARLES OLLEVENT, "bears grateful testimony to the benevolence of the founder."

The Chief has the wisdom to invest a large surplus capital in the construction of railways known as the "Blavnagar-Gondal" and the "Gondal-Parbanda" Railways. He is also a joint proprietor of the branch line known as Jetalpur-Rajkot Railway, which was formally opened for traffic by the Governor, LORD HARRIS. Jetalpur is a town belonging to Gondal. And this branch connects His Highness' capital with Rajkot, the Agency head-quarters on the one hand and with the main line on the other. It will thus be seen that the State has been very forward in promoting railways in the province.

The agricultural interests of the State have been stimulated in many ways, and every effort has been made to introduce superior wheat and new kinds of vegetables throughout the State. Irrigation by wells has been dealt with in a practical manner. New wells are being sunk every year. All this means increased revenue and prosperity, as well as safeguarding against local famine. The Gondal Horticultural Gardens are known all over Kathiawar. They are considered to be the best in the province, and are kept in excellent order. An agricultural class is also attached to them to enable agrarian youths to receive lessons, practical and theoretical, in the rural craft. Besides these, the State scholarships, schools, remissions of obnoxious taxes, grants of important concessions and privileges to his people, &c., are some of the works inaugurated by this intelligent young Chief.

He marked his appreciation of his *alma-mater*, the Rajkumar College, by giving it a handsome donation for

the purchase of books and book cases. A similar grant was given to the Bombay University for the collection of old Sanscrit manuscripts, and to the Oxford Indian Institute Building funds as well as to some other institutions of public importance.

These and other acts of the Ruler give unmistakable signs of a very bright and glorious future before him. As the vane shows the direction of the wind, as does the past decade's career of this able and worthy young Chief bear ample testimony to his capacity to rule his subjects right and well. It is no wonder that the State should advance in importance and prosperity by leaps and bounds under such a careful and well-meaning guide. It will not be amiss to note in this place that from the time of the British management to the present day the State has spent about £1,000,000 in public works, general improvements and railways. Besides the railways, it possesses 100 miles of metalled road, which is always kept in good repairs. The State owns nearly eighty schools, including Anglo-vernacular and vernacular schools, Sanscrit pathshalas, girls' schools, Urdu schools and night schools, all maintained at an annual expenditure of 30,000 rupees. His Highness has spent Rs. 2,50,000 on the education of boys and girls during the past ten years, against Rs. 1,30,000 spent during the past ten years of his minority, and the tendency is still on the increase. His Highness has, under contemplation, the establishment of a Girasia School at a cost of about a lac and a half of rupees for the benefit of the sons of petty landlords who are very backward in education. It is to be a boarding institution on the model of a public school in England.

The State supports two large hospitals and four dispensaries, including the travelling one. The medical department is under the direct supervision of His Highness, who takes considerable interest in its improvement by introducing many useful reforms and wholesome changes in the internal arrangement and general management of all the medical institutions of the State. His Highness has also recently created a new appointment of Health Officer, whose duties among other things, are to effect such measures of sanitary reforms as would tend to provide pure water, better drainage, proper conservancy and an efficient mode of disposing of filth. This is considered to be an important step in advance.

His Highness is the only State in Kathiawar which regularly publishes its annual reports. The telegraph connects his capital with the rest of the world. The State has a well-organised police, maintained at a yearly cost of Rs. 1,40,000, as also post offices, courts of justice, municipalities and various other institutions like those in the British territories.

The Gondal State is situated between latitude 21°58'N. and 21°7'S, and longitude 71°5'E, and 70°5'W. There are 174 towns and villages in the State with a population ranging from 200 to 20,000. The soil is about one-half of the taluka is black cotton soil and very good, whilst of the other half, in about three quarters, it is slightly inferior, and the remaining one quarter may be set down as bad. Gujarati is the language of the whole population, both Hindu and Musalman, but the Khojas and Memonas, when talking among themselves, chiefly use the Cutchi dialect. The chief manufactures of the State are cotton and woollen clothes, gold embroidered work, wooden toys and wood work turned on lathes and brass and copper utensils. The average rainfall is 25 inches, sufficient for all agricultural purposes. During the past year the ratio of births per 1,000 of population was 42.11 and that of deaths was 22.23.

His Highness exercises full civil and criminal jurisdiction over his subjects, who number 1,61,036 souls according to the last census. The area of his State is 1,024 square miles, yielding an average revenue of about Rs. 12,00,000. He pays an annual tribute of Rs. 1,10,721 to the British Government. His Highness has thought fit to introduce a change in the system of collecting land revenue in the State. For the time-honored system of recovering annual State demands of land revenue in kind is substituted the cash payment system, which seems to be popular with the cultivating classes.

The Chief is a man of studious habits and refined tastes. Everybody, high or low, can gain access to him at any time. This kind of accessibility has rendered His Highness popular among those who have to come in contact with him. He is fortunate in so far that he has a singularly gifted spouse in the person of RANI SHRI NAND KUNVERBA, daughter of the late Maharaja of Dharampore. She is a highly trained and accomplished lady, and takes the warmest interest in the educational advancement of her sex. She now and then onlives the occasions of prize-giving in the girls' schools of the State by thoughtful and practical remarks. We may be pardoned if we are tempted to quote the short but pithy advice she gave to the pupils of the Gondal Girls' School at a recent prize-giving. Her Highness expressed herself to the following effect:—

"Girls, this is the time for you to learn, you should make the best possible use of it. In ancient times many very learned ladies, such as MAITREYEE, GARGEE, LEELA, and others have flourished in our country. Keep their examples before your eyes. In the great philosophical controversy between MANDAMISHRA and SHANKARA CHARAYA, LEELA,—MANDAN MISHRA's wife,—was appointed umpire, with the consent of both the disputants. Her knowledge was so high that she was believed by the people to be an incarnation of SARASVATI or the goddess of learning. The erudition of MAITREYEE and GARGEE is well-known. Their words of wisdom are read with reverence by great pundits. Many other such instances can be cited from among our class. If their high standard of proficiency is difficult to reach, you should at least know as much of reading, writing, singing, keeping accounts, sewing, knitting, cooking and other domestic work, as is essential to your worldly requirements. Virtue and morality are equally essential—perhaps more so. For it is better to be moral and virtuous without learning than to become learned and be addicted to questionable habits. Where learning and virtue are found together, it is as good as 'gold with fragrance.' Therefore bear this in mind and zealously devote yourselves to study."

This accomplished lady accompanied her husband to Calcutta in December last, when His Highness attended the Indian Medical Congress as a representative of the Royal College of Physicians of Edinburgh whose member he is.

His Highness was elected Vice-President of the Indian Medical Association, and his deep interest in this body was shown by his presence at its inaugural meeting last year. His Highness has also recently afforded further concern in the welfare of the Association by giving a princely donation towards its Library Fund.

His Highness has three sons and two daughters, the heir apparent named BHONRAJ is twelve years old and is studying at Edinburgh, whence he will proceed to Eton in the course of a few months. His sister BAKUNVERBA, about eleven years old, is also prosecuting her studies at the Scottish capital. Her younger brother, only seven years old, will join her as soon as he is fit to begin his education.

We cannot close this memoir of so noble a member of our profession without expressing a heartfelt and prayerful wish that he may long be spared to rule his people in all prosperity, contentment and happiness—a wish that every member of our profession will repeat.

THE Indian Medical Record

1st March, 1895.

ANNUS MEDICUS, 1894.

As has been customary with it, *The Lancet* in its final issue of 1894 has favored its readers with an interesting compendium of all matters medical that have been transacted, or which have transpired during the preceding twelve months; and we take this early opportunity of condensing the same for the benefit of our readers.

In regard to *Medicine*, the attention of the whole world has been directed to influenza; and although the address of SIR GRAINGER STEWART before the British Medical Association showed that there are many lessons to be derived from the recent pandemic, there has not, on the whole, been much new light thrown on the nature of this disease. Though evidently due to a micro-organism, it cannot be accepted that the bacillus of PELLEFFER is the cause. We have, however, learnt something of the complications and sequelæ of the disease; and the investigations of Dr. PARSONS and of the Collective Investigation Committee of Germany have taught us much concerning the progress and spread of the disease. The Budapest Congress afforded the opportunity of gathering the experiences of all countries in regard to diphtheria, the KLEBS-LOEFFLER bacillus theory of which has been accepted; and the value of the antitoxin serum, as expounded by M. ROUX, is engrossing the attention of the clinical and pathological world. The investigations of Drs. MONCKTON, COPEMAN and KLEIN have verified the value of vaccination as a prophylactic for small-pox. KITASATO discovered, during the China plague of last spring, a bacillus which appears to be the cause of the disease. A monograph by Dr. OSLER and the discussions at the British Medical Association bear testimony to the value of cold in pyrexia and in typhoid fever. Surgical intervention in perforating gastric ulcer, a system of baths and exercise in the treatment of chronic heart disease, the use of bone marrow in pernicious anemia, and intra-laryngeal injections in pulmonary diseases are among the therapeutic successes of the year; while the clinical and pathological contributions are the study of albuminuric ulceration of the bowels by DICKINSON, RINGER on cardiac valvular disease, and COLEMAN on color hearing. The collected essays of SIR W. GULL, the clinical lectures and essays of SIR W. JENNER, SIR ANDREW CLARK on "Fibroid phthisis," CROCKER'S "Atlas of skin diseases" and CRIGHTON'S "History of epidemics in England" are some of the many additions to medical literature.

Surgery.—The tendency in the treatment of operation wounds has been towards asepsis as opposed to antiseptics, and the use in consequence of sterilised instruments and dressings. Abdominal surgery has progressed, resection of portions of diseased or injured bowel has often been successfully practised. Intravenous injection of saline solutions, chiefly where fall of blood pressure is due to excessive loss of blood and not merely to collapse, has been growing in favor. Mr. PITT'S successful ligature of the internal iliac artery by the transperitoneal method is

the first operation of its kind in England. In treating aneurisms of the extremities, attempts have been lately made with good results, to ligature the artery nearer the aneurism and not at a distance from the sac as taught by HUNTER. The ligature at a distance was advised, as there the vessel is more likely to be healthy than close to the aneurism, but the operation close to the sac has been attempted, as there is in it less likelihood of a return of pulsation, and as in amputations in elderly persons the arteries are often found to be extensively diseased where they have to be tied, and yet secondary hæmorrhage in those cases is rare. The treatment of aneurism by the method of ANTILLUS, ligaturing the vessel on both sides of the aneurism and excising the sac, has also been reverted to. Modern surgery has also lessened the mortality from strangulated hernia.

Obstetrics and Gynecology.—Symphysiotomy is gaining ground. In all cases that recovered from the operations performed (and the mortality has been very low) the consolidation of the pubis was sufficiently firm for the patients to walk about easily by the twentieth day. Professor PINARD concludes that symphysiotomy should be preferred to the induction of premature labor, but ought to be performed in those cases only where the separation of the bones to not more than seven centimetres will allow the passage of the fetal head at term. Professor LEOPOLD thinks the operation especially unsuitable for primiparæ, and also that the hæmorrhage during the operation and the lacerations of the vagina might occasion as much difficulty as the after-treatment. The operation is not favorably regarded by English obstetricians, but a large number of successful cases are reported from the Continent and in America. The radical treatment of uterine fibroids has of late given much better results than formerly, whatever the method of operation performed. Dr. HAULTAIN is in favor of the electrical treatment of uterine fibroids and subinvolution; but Dr. BERRY HART pronounces it tedious and disappointing. The general opinion of the Obstetrical Society of Edinburgh was decidedly against vaginal antiseptic douching as a routine practice during the puerperium.

Therapeutic Progress.—The event of the year in this direction has been the introduction of antitoxin serum. Papers have been read during the year upon the treatment of tetanus by antitoxin; and thyroid extract has been used in exophthalmic goitre, in sporadic cretinism, in lupus, psoriasis and malignant Indian syphilis. Bone marrow has been given with good results in leucocythæmia and pernicious anemia. Morphine, especially given with digitalis or strophanthus, has been found useful in heart disease. Apocynum cannabinum is said to have actions similar to those of digitalis. Arsenic in anemia, lemon juice as a hæmostatic, digitalis in chilblains, douching the nostrils with perchloride of mercury or boracic acid solutions in whooping cough, turpentine in incontinence of urine and senna in the incontinence met with in locomotor ataxy, have all been accorded a certain amount of value; epilepsy has been combated with bichlorate of soda and with adonis venalis given with bromides, and atropine during the intervals when bromides are not used. Phosphoric injections and iodides in locomotor ataxy, glycerophosphates in nervous depression, chlorobrom in sea sickness in conjunction with a

cholagogue pill and spare dry diet have been advocated, and lactic acid in the treatment of corneal ulcers, pentol as an anæsthetic less dangerous than chloroform, and neurodin and thermidin as antipyretics, are a few of the many additions to therapeutics that have been recorded.

Dental Surgery.—The Council of the British Dental Association has made vigorous efforts to put a stop to dental surgeons advertising themselves. Several deaths under chloroform used during the extraction of teeth have led to its employment in such operations being denounced as unjustifiable. Ceryl has taken the place of chloride of ethyl as a local anæsthetic. The administration of oxygen and nitrous oxide gas has been rendered more practicable by the introduction of Dr. HEWITT's portable apparatus. A connection has been supposed to exist between pyorrhea alveolaris and gout, and successful results have been claimed in the treatment of the former with lithium bitartrate internally given. Bridge work has had its place more clearly recognised.

Ophthalmology.—Egyptian ophthalmia has been further investigated by Professor FUCIS of Vienna, who has concluded that it is not a simple but a complex disease being in fact trachoma combined with active suppurative conjunctivitis or blepharorrhagia; the latter disease being the more dangerous of the two. It is remarkable that the gonococcus or microbe of gonorrhoeal ophthalmia is constantly present in the discharge. Many researches have been made upon the nervo-muscular apparatus governing the movements of the pupil. KNAPP has given a powerful stimulus to the method of extracting cataract without iridectomy, and adopted this plan in 91.4 per cent. of his last six hundred cases. The removal of the lens in cases of high myopia has been practised by PELGER and FUKALA. One eye alone should be operated on and the degree of myopia should at least require for its correction a lens of ten dioptries. Electrolysis and massage of the eye have been tried with partial success for the treatment of detached retina. At the Ophthalmological Congress in Edinburgh, LANDOLT warmly advocated the advancement of the yielding or less powerful tendon in strabismus in place of the treatment by tenotomy of the stronger tendon usually adopted. RUBENS and KOENIG have shown that the fovea centralis is color blind for the perception of blue.

Forensic Medicine.—A series of cases arising from carbolic acid poisoning were under treatment at the Royal Free Hospital between June and September, and eight deaths were attributed to this agent. Chloroform has been responsible for more deaths than the aggregate number referable to nitrous oxide gas, ether and A. C. E. mixture. The taking of the oath with the uplifted hand has made progress, and Mr. JUSTICE COLLINS recognising the danger lurking in the oft-kissed book, ordered the destruction of a Bible that an alleged syphilitic witness had kissed.

Anatomy and Physiology.—The modern methods of staining and mounting specimens for microscopic examination, and the use of very high powers, together with improvements in the application of photography to the microscope, have led to wonderful advances in our knowledge of the structure of true cells. A new method of discriminating and numbering the leucocytes of the blood has been described by Elisholtz which consists in adding

to specimens of blood a mixture of glycerine, eosine and gentian violet. The physiological action of allied compounds has been found to be in intimate relation to their chemical qualities, since the action augments with the magnitude of the molecular weight. The relations of the vermiform appendix and of the ureters have been carefully worked out. The interchange of gases in respiration have been shown to remain comparatively unaltered, notwithstanding great variations in the composition of the surrounding air. Professor HILL has shown that the position of the body materially alters the blood pressure in the carotid, and has thus established the influence of gravity on the circulation. Dr. RUSSELL has found that the hemispheres of the cerebellum are independent of each other, and that the impulses generated in each travel either to the spinal cord or to the cerebrum. It has been demonstrated that nerves are capable of acting on muscle and producing rapid rhythmic contractions in it even when it has passed into the condition of calaverie rigidity, for by employing the myophone it can be demonstrated that the excitability of the nerves persists as long as ten hours after death; whilst BROWN-SEQUARD has found that muscles affected with rigor mortis can contract and relax alternately though comparatively slowly. LOEB has shown that each part of an ovum does not form a special part of the embryo, but that fragments of the fully segmented ovum of one of the siphonophora may give rise to young and perfect animals.

The General Medical Council.—Held two statutory meetings: one in May and one in November. At the first meeting it was resolved that the examiners in surgery of the Apothecaries' Society, who are appointed by the Council, should be appointed for five years only, one retiring annually. The Council resolved to give a warning to certain institutions urging them to reconsider the terms in which the diplomas granted to midwives were framed. The names of seven practitioners were erased for professional offences. At the second meeting it was resolved to take proceedings against persons continuing to use the title attaching to qualifications of which they have been deprived by the licensing bodies. It condemned at this second meeting the issue of diplomas to midwives by the Obstetrical Society and other bodies, and intimated that from the present date it might be regarded as "infamous conduct in a professional respect."

Honors to Medical Men.—Surgeon-Major ERNEST HAROLD FENN of the Coldstream Guards was appointed a Companion of the Indian Empire, Sir F. SKYMOUR HADEN, Sir JOHN BUCKNILL, Sir THOMAS GRAINGER STEWART, Sir JAMES RUSSELL and Sir ARTHUR BENNICK are the medical knights that were created on the occasion of Her Majesty's fifty-fifth birth anniversary. Sir JAMES MOULT was made a Knight Commander of the Bath; Deputy Surgeon-General W. GEORGE MANLEY and Fleet Surgeon W. WHITE received the Companionship of the same order. Dr. ROBERT GRIEVE, Surgeon-General, British Guiana, received the Companionship of St. MICHAEL and St. GEORGE. Surgeon WALTER BOWDEN received the distinguished service order. Sir JOHN WILLIAMS received a Baronetcy, and Dr. LEANDER JAMESON the Companionship of the Bath.

**THE REPRESENTATION OF THE EURASIAN AND
ANGLO-INDIAN ASSOCIATION TO THE
GOVERNMENT OF INDIA ON
THE MILITARY ASSISTANT
SURGEONS' SERVICE.**

In the *Eurasian and Anglo-Indian Recorder*, we find the following extract from a report of the proceedings of a special meeting of the Board of Directors of the Eurasian and Anglo-Indian Association, held at the Doveton College, Calcutta, on the 4th February, 1895:—"In speaking to the notice against his name, Dr. JAMES R. WALLACE referred to the request made to him by Surgeon-Major-General W. R. RICE, M.D., C.S.I., the Surgeon-General with the Government of India, that the opinion of the Board of Direction be submitted to the Surgeon-General "as to whether European and Eurasian lads, who have passed the Entrance Examination of an Indian University, could be obtained in sufficient numbers to meet the need for candidates for the Military Assistant Surgeons' Service." Dr. WALLACE said the Government had given tangible proof of its appreciation of the loyalty, devotion and ability of this class of its servants, and had already favored them with an appropriate change in their professional designation, besides promising them a suitable increase in their salary. Dr. WALLACE said that it was desirable if any raising of the standard of preliminary education was adopted, that such a measure would of necessity entail a greater expenditure on the education of lads who sought admission into the medical service, and that the Board under the circumstances should seek from Government some commensurate advantage for the community they represent. He would suggest that a full professional training, a recognised degree in medicine and enhanced pay for the various grades be asked for by the Board in an immediate representation to Government on this subject.

Mr. C. E. DISSENT supported Dr. WALLACE's views, and the opinion of the meeting was expressed to the effect—"that the Government would find no difficulty in getting lads who had passed the Entrance Examination in sufficient numbers for the needs of the Military Assistant Surgeons' Service."

It was resolved that Dr. WALLACE and Mr. DISSENT be constituted a Sub-Committee to prepare an immediate representation to Government through Dr. RICE on the subject, and that it be circulated for approval."

The following representation prepared by the Sub-Committee was drafted and circulated to the Directors, and after receiving the cordial approval of the majority, was signed by the President, Mr. W. H. RYLAND, and submitted to Surgeon-Major-General W. R. RICE, M.D., C.S.I. on the 18th February 1895.

From THE PRESIDENT,

Eurasian and Anglo-Indian Association.

To SURGEON MAJOR-GENERAL W. R. RICE, M.D., C.S.I.,
Surgeon-General with the Government of India,

SIR,

DR. J. R. WALLACE, one of the Directors of this Association, having communicated your request to be favored with an expression of the opinion of the Board of Directors of the Eurasian and Anglo-Indian Association on the question "whether Government could obtain young

men of the domiciled European and Eurasian community who have passed the Entrance Examination of an Indian University in sufficient numbers to meet the demand for candidates for the Military Assistant Surgeons' Service," I have the honor to state for your information that the Board of Directors having given all the circumstances connected with the present system of recruitment for this service their careful consideration, are of opinion that the Government of India would find no difficulty in obtaining a sufficient number of suitable candidates for this service who have passed the University Entrance Examination, and that the raising of the educational standard for admission into this service would lead to its recruitment not only from a better educated but a superior class of men. The Board of Directors of this Association have recognised with much pleasure, the appreciation by Government of the services of the Military Subordinate Staff as evidenced by the recent improvement of their status and professional designation, as well as the promised enhancement of their salary. The Board also observes with satisfaction the loyalty and cheerful obedience which have always been evinced by the men of this service under varied and trying circumstances, and they feel that in the Military Assistant Surgeons, the devotion of the Eurasian and Anglo-Indian community to the Government has been signally exemplified. Influenced by a sincere desire to aid the Government of India in any plan by which the services of the community which the Board represents may be utilised with advantage to the State, the Board would seek to approach the Government of India with the following suggestions for the improvement of the Military Subordinate Service, having special regard to the circumstances that the improvements now suggested will relieve the Government of the financial burden of maintaining a paid Military student class, and will offer an easy means of suitably increasing the salaries at present paid to the various grades of Military Assistant Surgeons which Government has already generously promised to raise.

The suggestions are:—

1. That the educational standard for admission to the Military Assistant Surgeon class be, and continue to be, the Entrance Examination of an Indian University. It is considered that the raising of the standard of general education preliminary to a professional training will undoubtedly lead to higher professional ability and efficiency.
2. That the course of medical study be extended to five years and that it be the complete university curriculum for the degree of L. M. S. It is felt in this direction that as Military Assistant Surgeons are largely utilised in the medical charge of civil stations and other independent and important charges, the Government should place its servants of this class in a position in which their professional qualification would be unassailable, and this it is believed can best be done by insisting on a complete and thorough medical education, such as graduates receive, and by their securing the hall-mark of our Indian universities.
3. That students of the Military Class be specially permitted by an enactment of Government, and compelled by a rule of the service, to appear for and obtain the

diploma of L. M. S. of an Indian University, without which they should not be considered qualified for appointment as Military Assistant Surgeons. Inasmuch as the Indian Universities require that candidates for the degree of L. M. S. shall have passed the educational standard of the First Arts, it will be necessary for Government to arrange that its military students be permitted to appear for the L. M. S. examination, and if successful, receive the L. M. S. degree. The possession of a recognised diploma of an Indian University by its Military Assistant Surgeons, will be of obvious advantage to the State in fixing the standard of qualification needed for the service in those higher posts where their independent judgment and care of the sick are often called into action.

4. That having obtained the diploma of L. M. S., such candidates be appointed Second Grade Assistant Surgeons on a salary of Rs. 85 per mensem, thus abolishing the present Third Grade Assistant Surgeons.

5. That admission to the Military Assistant Surgeons' Class shall involve the following requirements:—

(a). Eligibility under the existing service regulations as regards physical fitness, age, parentage and character.

(b). That candidates shall have passed the Entrance Examination of an Indian University.

(c). That successful candidates shall be admitted into the Military Assistant Surgeon Class, and shall be educated free by Government for five years.

(d). That they shall board, lodge, clothe and provide themselves with necessary books and appliances for study at their own expense and that Government will bear no part of the cost of their maintenance during their five years course of study.

(e). That candidates, or their guardians on their behalf, shall bind themselves to serve Government for a term of years, in return for the free education given by Government, and should a candidate refuse to enter Government service after completing his medical education, he shall be liable to pay the sum of Rs. 1,000, to reimburse the State the expenses of his education.

6. That from the savings effected by Government by the abolition of monetary, residential and other forms of support, as at present afforded to the Military Class, a portion be appropriated for raising the present grade salaries of Military Assistant Surgeons, thereby redeeming the promise of Government, and at the same time rendering the service more attractive to the better class of men who under its altered conditions would readily seek admission to it.

The Board of Directors trust that this communication may receive your kind, considerate, and early attention.

I have the honor to be

Sir,

Your most obedient servant,

W. H. RYLAND

President, Eurasian and Anglo-Indian Association.

This document is of considerable import and known not only to the Military Assistant Surgeons' Service, but to the whole domiciled Anglo-Indian and Eurasian community of India and Burma, which form the recruiting ground for its ranks. It involves a whole-sale revolution

in the conditions of admission into the service, and demands therefore the serious attention of the community whom it concerns.

We have been asked,—Is the game worth the candle? And we are inclined to answer both yes and no. Yes certainly and assuredly, if the Government makes the service sufficiently attractive in its pay and prospects. The negative has already been proved to the Government in the difficulties that have presented themselves in obtaining a lower grade of candidates than those referred to in the representation now before Government. As the service now stands, it offers poor prospects to the standard of men who at present tardily seek admission to its ranks, and of this fact the Government has had abundant evidence. If candidates are to be found for the service, even as it stands, we feel that the State ought to fulfil its pledges and enhance the meagre emoluments of the various grades and at the same time remove the term *SUBORDINATE* from the Service designation. Despite the SHAKESPEARIAN dictum, "What's in a name," we venture to say with all earnestness and truth that the gift of the altered appellation from Apothecary to Assistant Surgeon has been robbed of nearly all its grace and gratification by the reintroduction of the term *Subordinate* as a service designation. Consistency and policy both urge the need for expunging the offensive name "subordinate." We would simply ask those in authority to shew us a single subordinate officer of the Commissariat, Public Works, Military Works, Ordnance, Engineers or other State service, that signs himself a member of a *Subordinate* Service. They are all members of the "Army Commissariat Department" or the "Public Works Department," and so also are Assistant Surgeons members of the INDIAN MEDICAL SERVICE, subordinates though they are, as their class designation sufficiently and emphatically implies. We would earnestly appeal to Surgeon Major-General RICE to remove the term *Subordinate* as the official designation of this service. With this galling stigma abolished and the salaries—chiefly of the lower grades—improved, we are in hearty accord with the suggestions of the Eurasian and Anglo-Indian Association that the educational standard of admission be elevated to the University Matriculation test, that the professional course be enhanced to five years, and that the professional test for the rank of Assistant Surgeon, Indian Medical Service, be the L. M. S. degree.

Such changes, if generously sanctioned by the Government, would be a boon to India in more ways than one.

With regard to the abolition of the *paid* military class, and the enhancement of the salaries of the various grades, we have been asked to respectfully and earnestly entreat of the Government to allow the payment of the military class to remain unaltered if it can possibly do so, as the aid thus given by the State to the Anglo-Indian community is the *only* instance out of many forms of state support given to other Indian communities. Substantial precedents have been brought to our notice, for retaining the present system of *paid* military students, but for the present we would simply urge the argument that the Government can, with a greater show of reason and justice, maintain a *paid* class under the altered conditions of a higher degree of classical and professional requirements as a *paid* *pro quo* than under the present regime, where less is given for the money expended. And

with regard to the enhanced salaries, we would, with all grateful appreciation for its generosity and liberality, respectfully remind the Government, that its own recommendations for the enhancement of the salaries of the lower grades were as follows:—2nd grade Assistant Surgeon (the third grade being abolished in the same recommendations) Rs. 125—over 7 years in this grade, Rs. 125—1st grade Rs. 150, over 5 years in this grade Rs. 200.

We are well aware of the financial pressure under which the Government of India labors at present, and we know also the urgent need there is for augmenting the numbers of the Military Assistant Surgeons' Service to meet the exigencies of the State, yet we feel that as long as all other European subordinate services offer better attractions to our youths in the way of salary and prospects, recruitment difficulties will remain, though the Government may, without much expenditure, remove the difficulties by enhancing the salaries of the lower grades of Military Assistant Surgeons and enforce reform by demanding higher educational and professional attainments as a *quid pro quo* for the improvements it makes.

We would earnestly invite the co-operation and help of the sister associations in other provinces and presidencies in this matter, so as to aid the Government in solving the difficulties which surround the urgent reforms that are so pressing needed, both for the service and for the community they represent.

COMMENTS AND NEWS.

THE REPRESENTATIONS OF THE INDIAN MEDICAL ASSOCIATION ON THE GRIEVANCES OF CIVIL ASSISTANT SURGEONS AND HOSPITAL ASSISTANTS.

WHILE the press throughout India has spoken with no uncertain sound its unqualified approval of the suggestions made by the Indian Medical Association to the Government of India for the redress of the grievances of Civil Assistant Surgeons and Hospital Assistants, and while it is gratifying to learn that these representations have been forwarded to the Government with the cordial recommendations of its chief medical advisers, it is worth a good deal to find Indian politicians of every shade of opinion so thoroughly on the side of the Indian Medical Association in commending its action as politic and to the point. We find the HON'BLE MAHENDRA LAL NINCAR, M.D., C.I.E., in the *Calcutta Journal of Medicine* after reproducing *in extenso* the representations of the Association, writing thus:—"We have great pleasure, in this number, to give publicity to the representations of the Indian Medical Association, 'on the grievances of Civil Assistant Surgeons and Civil Hospital Assistants.' They do not pray for a commission of inquiry, but they offer certain suggestions to Government for the improvement of the status, pay and pension of both these classes of public servants.

With regard to the Assistant Surgeons, we repeat that their grievances are real and sorely felt, and unless remedied the deterioration of the service will follow as a necessary consequence. Neglected, ill-paid, with no prospects (except the wretched and miserable Rai-Bahadurship, which has ceased to carry honor or distinction) this class of public servants are maintaining up to the present day the high standard of knowledge and skill, of devotedness in their official career, of deep sympathy with suffering humanity, and of loyalty to Government, which have distinguished them ever since their

creation by the establishment of medical colleges in India on the model of the West. But the times are terribly hard, and it would be too much to expect that with bare necessities and half-starved families, these men would continue to maintain their position as they have been hitherto doing.

"We are entirely in accord with the suggestions made by the Indian Medical Association, even as regards the changes in designation. For, Shakespeare notwithstanding, there is much in a name, and we have no doubt that the changes suggested are what the real positions of both the Assistant Surgeons and the Hospital Assistants legitimately demand, and would, with increased emoluments, help in improving their status and their quality as well. In our opinion Government cannot do better than adopt the suggestions which will, it is true, entail some additional cost to the State, but this will be more than compensated for by considerably improved efficiency of the services in question. It would be bad policy, on the part of Government, and uneconomical in the long run, to create discontent in the minds of two most useful classes of its servants."

DOCTORS MAY KILL IN SOME CASES!

THERE are few journals, lay, religious, or professional, which will not join *The Indo-European Correspondence* in protesting against the suggestion of the *Civil and Military Gazette* that, in some instances, "an exception may be made to the salutary rule that a doctor's mission is to cure, not to kill." The *Gazette* is of opinion that before long there will be a "legal enactment authorising medical men to take life in certain cases." The astounding absurdity of such a proposition leads us to imagine that our civil and military contemporaries was cracking a grim joke against the medical and religious sections of Christendom. He thinks the cases and the conditions in which, medical men may put an end to the existence of suffering humanity can be infallibly recognised and categorically laid down and defined. Medical men can however only prognose favorably or unfavorably; and although in a few extreme cases we may be able to positively anticipate a fatal termination, yet there are a very large number of cases presenting the most unfavorable aspects, and which, according to our limited mortal ken, appear to be in the most hopeless conditions, and which withal mend and recover. The ever-increasing additions to medical science tell us that many diseases which though now regarded as absolutely fatal or incurable may, in a few short years, come within the scope of medical relief and cure. Are we then to seriously entertain the idea that, because our limited knowledge of the mysteries of life incline us to the belief that such and such a suffering mortal is incurably ill, his life may be speedily terminated with benefit to himself and to others? Had such a preposterous enactment been made a few years ago, how many persons who are now in health and vigour, or who are at least leading lives of usefulness and activity may have been consigned to untimely graves? Is it not by acting on the principle of "while there is life there is hope," and by the dogged perseverance of medical men even in the apparently most hopeless cases that discoveries, either made by chance or scientifically deduced, have been effected, giving relief and life to the sufferers and to those who may be similarly affected in the future? It is however quite unnecessary to give any prolonged or serious consideration to the suggestion so surprisingly put forward by our contemporaries, for no Christian Government will ever commit itself to such an enactment to persuade medical men to determine whether their unfortunate patients are to be allowed to take their chances of living or to be hurried into eternity.

THE UNCOVENANTED MEDICAL SERVICE.

A correspondent, with the nom de guerre "MABAGRASS," writing to the *Indian Daily News*, begins by certifying former letters on the subject by "A. I. Bala," "M. S., M. D. C.," and "A member of the Uncovenanted Medical Service," respectively, and then goes on to say, "the subject-matter of these three letters however refers to the Uncovenanted Medical Service." The Assistant Surgeons referred to in the third correspondence's letter, the latter does not seem to understand are all university graduates which is NOT the case with all members of the Indian Medical Service which, after admitting he is a member of, the correspondent is questioning eulogies. These Assistant Surgeons are quite as capable of doing justice (in civil appointments) to their position as many members of the Indian Medical Service. "MABAGRASS" does not wish to be understood that the Indian Medical Service has no merits.

He then goes on to give a short history of the inception and present condition of the Uncovenanted Medical Service. It was started, he says, in 1867—with the object of creating appointments in the various medical colleges in India, and other uncovenanted appointments, for civil medical relief, throughout the country. It was created as a counterpart of the uncovenanted branch in the Revenue, Judicial and other departments of the public service, to give scope to local talent only. But since the carrying out of these objects has been placed in the hands of military medical officers, the appointments have been wrested and smuggled into what are now said to be *privileges* of the service. Further, the Uncovenanted Medical Service is mainly recruited by *imported* talent, and thus the Uncovenanted Medical Service has to "all intents and purposes, become a dead-letter."

The Indian Medical Service has no claim to absorb civil posts, or to engage in private practice, as is now the case. The Indian Medical Service covenant is a purely *military* one; it neither guarantees nor makes mention of any civil posts for its members.

In conclusion "MABAGRASS" believes the time is not distant when the present condition of the working of the Uncovenanted Medical Service will be brought to light as one of the greatest scandals of the day; that local talent will be recognised by Government, and the claims of the local profession will have to be listened to. He reiterates the fact that Indian medical graduates have proved themselves in every way the equals of their *Western* brethren, and are in no way behind them. But it is only through jealousy and selfishness of their being *locally* trained, they are subjected to such "monstrous and unbecoming degradation," against which the local profession and the people of this country should protest.

ADDRESS TO DR. ERNEST HART BY THE MEDICAL PROFESSION OF HYDERABAD.

AFTER welcoming DR. HART to Hyderabad, the capital of the Nizam's Dominions, an address given him by the people adverts to the fact that, under his editorship, the *British Medical Journal* has secured 15,000 members and 18,000 readers all over the English-speaking world. Through its influence the bulk of medical opinion is guided, while the large number of members is but the public expression of confidence reposed in him by the profession. The *Collective Investigation Record* of the Association owes its origin to DR. HART's untiring labors. His *Essays on State Medicine* have a wide influence, and especially his works on the *Compulsory Notification of Infectious Diseases* and the *Nursing of Cholera, its diffusion and extinction*. DR. HART has also labored for the good of the profession, and has con-

tinued to reduce the abuses and defects found therein, bringing to light all cases of individual delinquencies and breaches of medical ethics. The works which have been guided to a successful termination through his influence are sanitary reform, the mitigation or arrest of infectious and contagious diseases, the intimate connection between polluted milk and enteric fever, diphtheria and scarlatina, (as being the first to point out this connection) ameliorating the sanitary condition of the poorer classes in England, as Chairman of the Parliamentary Bills Committee, he has effected the introduction of notification and additions to the sanitary law of the realm. Lastly, DR. HART has displayed great ability and judgment in dealing with the most important question of the connection between the pilgrimage to Mecca, and the dissemination of cholera throughout the civilised globe. This is certainly amongst the greatest undertakings of the medical profession of the 19th century. This subject was dealt on at length in the address coupled with DR. HART's special fitness to carry his mission to a successful issue. With the address was presented a silver casket. DR. HART replied in an exceedingly graceful and agreeable little speech in which he referred to the insignificant reception accorded him, and alluded to the special cause of his visit, the introduction of sanitary reform to enable pilgrims to perform the sacred duty of visiting the holy city without the risk of cholera.

INFANT NEGLECT, INSURANCE AND MORTALITY.

THE more closely we examine the practice of child insurance the less there is in it to commend it. Notwithstanding the fact that illness and disease are far more prevalent during child-life than in later years, it does not by any means follow that DEATH is their natural and certain outcome in each case. Indeed if properly tended, nourished and promptly treated when ill, which is now possible for a mere pittance, there is great hope of infant life. Life, rather than death, should be the natural desire of each parent for its off-spring. The loss, even pecuniary, entailed by an infant's death is so incalculably small, and the funeral arrangements and expenses connected therewith so simple and trifling, that they could easily be met by the poorest family brought up and maintained by thrift and honest labor. Necessity for insurance of child-life therefore, to recover such a pittance, is quite superfluous. But the persons who seek such insurance are prominently characterized by their neglect towards their off-spring and a self-indulgence, which is not less criminal. During one month over 4,000 children were subjected to cruel treatment, and the organ of the *National Society for the prevention of cruelty to children* reported that over one-third of that number were insured. In face of such facts, and in order to reduce to a minimum the evils of infant insurance, drastic reforms should be resorted to, such as (1) "the sum insured should no more than discharge the bare cost of funeral arrangements, and (2) evidence of such criminal neglect or mismanagement as might account for a child's death, should disqualify for the receipt of the sum insured."

Medical men would do well to refuse scrupulously and absolutely, to grant the customary death certificate in cases where they believe such ill-treatment or mismanagement has occurred.

ABOUT FLEAS.

EVERY ONE knows everything about the flea, but few indeed know anything concerning it, beyond its bite, its jump and its disappearance. Barely an animal exists but has its own particular flea to feed, yet they all belong to the same species and with trifling differences as to its habitat and habits, have practically the same life history, and not one of them can come into existence if there is no dust about for the larva to

and upon. The first lays from 4 to 10 and eggs (0.5 mm long) which hatch within endless grubs. These grubs consist of 12 white segments, each provided with long sensory hairs, and the last one also carries 2 stiff spines to assist locomotion. The head appears as a yellow sphere crested with a small sharp spike and fitted with a pair of strong mandibles by which the larva feeds on decaying animal and vegetable refuse. On or about the 15th day after birth the larva encloses itself in a silken cocoon within which it undergoes profound changes, and on the 18th to the 19th day emerges as the familiar and very lively insect, which is only an occasional parasite that makes use of man and other animals mostly as a lender or provision store, and seldom lives beyond 28 months. The varieties most known of these pests are:—*Palae irritans* affecting man, *P. serraticornis* the dog and cat; *P. artem*, birds; and *P. ginsengophalus*, the hare and rabbit; but strange to say the monkey has no flea peculiar to it. The fleas that attack bats, rats, and mice, belong to an entirely different genus (*Typipylus*) in which the eyes are either absent or very small and the body longer than in the *palae*. Moles and humble bees are associated with a third genus (*Hydrirapilla* *abrupticeps*) whose body is large (3.5 to 5.5 mm) and particularly hairy, while the head which is short and rounded is devoid of eyes.

DR. HART ON PILGRIMAGE.

DR. HART addressed a large gathering in the public gardens of Hyderabad. The Minister presided, while the Resident, the leading nobles and religious dignitaries were present. After being introduced by the Minister, DR. HART addressed the meeting, his address being ably translated by SYED ALI. He began by giving a historical sketch of cholera in England, Europe and India. Cholera, he said, was due to impure water and bad food and therefore preventable. The pilgrims to Mecca, owing to bad sanitary arrangements, spread the disease all over the world. Eight hundred thousand pilgrims visit Mecca annually, but absolutely nothing has been done to ensure sanitation, nor the comfort of the pilgrims. There is quarantine at Kanara, Jukla and Laila, but no accommodation whatever. They drink filthy water and eat bad food—the main thing happens on their line of march—putrifying carcasses of man and cattle lie the road and contaminate air and water. At the halting stations again there are no sanitary arrangements, and pilgrims die of cholera in thousands. In introducing sanitation, no interference need be made with religious customs. A resolution was carried to urge the Nizam's Government to send out qualified Mahomedan doctors with pilgrims to submit a report of the conditions to the Nizam to address the Sultan of Turkey for co-operation. The object of the scheme being to help the Mahomedans and not to interfere with the sacred Lemken well, and hence it should secure the support of the Mahomedan world.

THE DISSEMINATION OF CHOLERA BY RAILWAYS.

SURGEON-MAJOR LEWIS has made an enquiry into the alleged influence of railways in disseminating cholera. He finds that there is no ground for such a belief; for were it so, cholera would be manifested much more frequently and would more rapidly be carried about from place to place than it was in pre-railway days. (An individual case or so may be thus carried, but it does not bear any influence on the after-course of the epidemic). Then again cholera would invariably follow the lines of railway and be more frequent and more severe there than in districts far removed—but such is not the case; the outbreak, as a rule, proceeds in a very erratic and irregular manner. On the other hand, Dr. LEWIS

believes that railways exercise highly beneficial influence in preventing and checking the dissemination of cholera for two reasons:—

(1) They are "a great safeguard to those who are there in order to escape from an infected locality."

(2) "They are the quickest means of dispersing a large collection of people from any place in which cholera has appeared."

In explaining the fact that when pilgrims depart to thousands of villages from infected districts and on returning most of them escape, only a few hundred cases taking the disease, he points out that "the local epidemics are due to some cause peculiar to the villages affected, and not common to the thousands that escape."

THE BENGAL HEALTH SOCIETY.

LADY ELLIOTT called together a meeting of the above Society at Belvedere. It was resolved that the said Society should not be affiliated to the National Health Society, because, while the objects of the two are the same, the conditions under which they work are widely different. The Bengal Health Society is essentially a provincial one, as its name implies. Mrs. WHEELER (Inspector of girls' schools for Bengal) was appointed Secretary, Dr. JOUBERT, Honorary Treasurer (*pro tem.*), while Mrs. GANGULI, M.D., is to prepare a treatise or brochure on the management of children, adapted to the needs and understanding of Bengalees. Dr. GANGULI will revise certain placards of the English Health Society adapting them to India. They will be hung up in zenanas and schools and will in addition be made as attractive as color and design can make them, besides being instructive.

Surgeon-Colonel HARVEY gave some very valuable hints as to the best way of carrying on the work, and suggested that pamphlets on domestic sanitation, water, the care of milch cows and the prevention of small-pox and fevers, &c., should be simply written, translated into Bengalee and widely distributed.

The Society may indeed be well congratulated on its plucky effort in beginning a warfare against centuries of accumulated ignorance and prejudice as to sanitary matters in Bengal.

THE ARMY MEDICAL STAFF AND THE INDIAN ARMY CORPS.

It is now announced that the principal medical officers of the army corps will each get Rs. 2,000 per month. The Secretary or "personal assistant," as he will be called if on the British service—will get Rs. 150 extra per month; if of the Indian service, consolidated pay of Rs. 600 per month. This clearly shows that the Surgeon-Major Generals of the Army Medical Staff, who may be nominated to principal medical officer-ships will lose Rs. 300 each month, and, with the rupee at 1s. 4d., will, although ranking with Major-Generals, get less pay than Brigadier-Generals. In short, a Surgeon-Major-General, at the present rate of exchange of rupees, would be better off at home than in India. The misfortune that has come on the Army Medical Staff in the new organization was foretold long ago.

DEATH OF THE CHAMPION CENTENARIAN.

THAT famous veteran, Lieutenant NICOLAS LAVIN of the Grande Armée passed away at Saratoff at the age of 123 years, leaving a daughter aged 78 to mourn his loss. Born in Paris in 1763, he served as a hussar through a number of campaigns till he was taken prisoner in 1812, during Napoleon's retreat from Moscow. Instead of returning to France when liberated he married and settled down as a tenant of 500 a. Here he lived ever since, and in 1877 he celebrated his centenary with a present of 1,000 roubles.

CONSUMPTION: "BOUGHTING IT VERSUS THE CODDLING TREATMENT."

"*Beware of draughts*" is the eternal cry of most writers on health; but "air is the best medicine of all," says Dr. CHAS. E. PAGE, and throwing wide open every door and window to thoroughly ventilate the house orders the consumptive patient to camp out all the year round, so that in the fight for his life the patient may not hazard his chances by any letting up in the medicine (*i.e., fresh air*) of which he requires a *profusion* to secure a return to health. As proof of the rationality of this treatment, he cites quite a number of convincing cures and inveighs on the patient the necessity for adequate exercise, moderation in clothing, telling him to warm himself with a little shaking up rather than by a top-coat in winter and cautioning him against chills suggests that as soon as a consumptive patient comes in from his outings in cold weather, he should seek his chamber with its *always wide-open windows* and lie down with plenty of blankets for protection; but he must on no account hang over a fire for warmth or sit about, for sitting is unnatural, and the less he does of it the better as pure fresh air is *all* he requires and he cannot get too much of that even when he is "out of the woods."

NEW A. M. S. AND I. M. S. SURGEONS.

THESE lists show the positions and marks obtained at the Netley and London competitions by the following probationers who are now admitted into the service:—

| British. | | Indians. | |
|--------------------|-------|-----------------|-------|
| Harrison, W. B. | 5,052 | Milne, C. J. | 5,625 |
| Howell, H. A. L. | 4,931 | Beynon, A. F. | 4,971 |
| Lawson, D. | 4,893 | Bentley, C. H. | 4,945 |
| Steel, R. B. | 4,716 | Watling, P. H. | 4,768 |
| Proffitt, C. W. | 4,561 | Ryans, S. | 4,631 |
| Kiddle, F. | 4,188 | McMillan, J. D. | 4,531 |
| Shaddan, H. E. | 3,983 | Gwyther, A. | 4,406 |
| Whitehead, J. H. | 3,877 | Morgan, E. J. | 4,458 |
| Marrison, J. A. | 3,837 | Ward, A. E. F. | 4,391 |
| Tomlinson, L. P. | 3,744 | Carr, W. | 4,313 |
| Perry, S. J. C. P. | 3,614 | Hamilton, J. A. | 4,252 |
| Heaton, A. F. | 3,552 | McDonald, J. H. | 3,918 |
| | | Wall, F. | 3,922 |
| | | Mathew, C. M. | 3,758 |

MEDICAL COURAGE HONORED.

DR. MARY BRADFORD, an American Missionary to Persia, is about to receive the highly complimentary present of a hospital, to be conducted by herself. It is the outcome of her very courageous course during the cholera epidemic of 1892. She remained at her post through the entire epidemic. Some wealthy merchants, who recognised the heroic qualities of the lady's conduct, have undertaken to build and equip this hospital as a reward of merit.

THE MISSING LINK.

DR. EUG. DUBOIS, of the Dutch Indian Army Service, believes that he has found the missing link between *homo primus* and the anthropoid apes in some fossil remains recently discovered in the andesitic tuffs of Java. The bones consist of the upper part of a skull, a very perfect femur, and an upper molar tooth. The remains are elaborately described and figured in a quarto memoir recently published in Batavia.

A DOCTOR FOR KABUL.

ASSISTANT SURGEON AMIR SHAH of Lahore has accepted service with the Amir of Afghanistan, who was so anxious to secure him, that the doctor has been engaged practically on his own terms. In addition to obtaining his professional advice the Amir intends to utilize him in establishing a medical school at Kabul.

NEW MEMBERS OF THE INDIAN MEDICAL ASSOCIATION.

We have pleasure in publishing the names of the following gentlemen who have joined the Association since our last issue:—

Fateh Chand, M.B., B.S., L.D.S. (Dur.), L.R.C.P., L.M.A. (Lond.), L.M.S. (Punjab), Medical College, Lahore.
V. M. Carleton, Asst. Surgeon, I. M. S., Fort, Agra.
Ram Chandra Mozumdar, L.M.S., Asst. Surgeon, No. 1/1 Nilmoney Duff's Lane, Calcutta.
Hara Kali Sen, V.L.M.S., Asst. Surgeon, Raiganj, Dinajpur District.
Batakram Mehta, L.M.S., Baroda.
Balabhai, L.M.S., Baroda.
Dhirajram, L.M.S., Baroda.
Dhume, L.M.S., Baroda.
Miss A. M. Dunn, M.D., Baroda.
B. S. Shroff, L.M.S., Baroda.
Tafsool Hossein, Hospital Assistant, Hoolingpoorie, Jerbat.

Medical men and women in all parts of India and Burma who desire to take a share in aiding the advancement of the Indian Medical Association are cordially requested to write to the Editor of the *Indian Medical Record*, and he will gladly send them blank membership forms and prospectuses. We are glad to find many willing volunteers.

SHORT ITEMS.

The day is long past when children can be kept innocent through ignorance. The innocence of virtue, the knowledge that will give them power to choose the pure and good, is the only fortification that can protect them from the dangers and evils of social impurity.

It has been computed that the death rate of the globe is 66 per minute, 97,790 per day, or 35,717,790 per year. The birth rate is 70 per minute, 100,800 per day, or 36,817,200 per year, reckoning the year to be 364½ days in length.

Surgn. Lieut.-Col. F. C. Barker M.D., F.R.C.S.I., I. M. S., Dr. Behramji Naroji Dabshi G.M.C., Surgeon Lieutenant-Colonel W. McConaghy, and Surgeon-Captain Quick, I. M. S., have been appointed Fellows of the Bombay University.

Surgeon-Colonel D. O'C. Baye officiates as Principal Medical Officer, Presidency District, and will relieve Surgeon-Colonel Cleghorn in the charge of the Panjab on Dr. Rice's retirement.

We much regret to report that Mr. Burroughs of the well-known medical house of Burroughs Wellcome and Co. of London died on the 6th February at Monte Carlo from pneumonia.

Surgeon-Colonel Plicher, Inspector General of Civil Hospitals, N.W. Provinces, retires on 29th March, being succeeded by Surgeon-Colonel Warburton.

To detach a fish-bone from the throat, swallow a raw egg as quickly as it can be obtained.

Surgeon-Major J. Sykes has been given a year's extension as Civil Surgeon of Mussoorie.

Helen Lander of Bombay has passed the L.M.S. examination and has succeeded in winning the Cama gold medal.

Surgeon-Major H. Martin M.B., A.M.S., is appointed surgeon to H. E. Lord Sandhurst, Governor of Bombay.

Current Medical Literature.

MEDICINE.

The Nature and Treatment of Leprosy.

DR. H. BLISS, in an interesting article in the *American Journal of the Medical Sciences*, mentions the above subject. He has collected with reference to the presence of bacilli, 80 cases of erythematous and 5 cases of nodular leprosy.

He has found bacilli in sections of tubercles, blood drawn directly from tubercles, (not in blood current), discharges from leprosy ulcers, and spores, and some secretions (only occasionally). But he has failed to discover them in the sweat, the urine, and the general blood current.

As to the treatment of leprosy, he finds that preparations of arsenic, mercury and iodine are utterly useless, except in cases due to syphilis. The remedy which in his hands has been so pre-eminently useful is *chauliogra oil*. Although Dr. BLISS cannot assert positively that he has effected a complete cure in any single case of leprosy, yet he has seen such marvellous results—such as he was little prepared to witness—follow the proper use of the above oil, as to justify its sole employment in leprosy. If begun early in the disease (with improved diet and personal hygiene,) and continued uninterruptedly right through the three stages, it will "cure the patient in many instances." He begins with 10 minims of the oil in gelatine capsules after each meal, taken in a glass of milk, the dose being gradually increased until 1 to 2 drachms are taken daily (3 drachms daily are apt to set up diarrhoea), at the same time the patient is bathed with warm water and soap every alternate day, and the oil is warmed and rubbed all over his body and into the tubercles and maculae. Of course many cases are found to be intractable, but if begun early and continued as detailed above, it will never fail to produce notable improvement, especially in the tuberculous stage. Under it he has seen "tubercles absorbed, anaesthesia removed, eruptions disappear, ulcers heal, pulses quieted, suppleness and elasticity of the skin restored, and hope replace despair."

Symptomatology of Syringomyelia.

BRANNON reported where syringomyelia arising from syphilitic tumors of the spinal cord showed wasting, loss of motion, power and sensation and resulted in death when the post-mortem disclosed two syphilitic tumors on either side of the transverse sulcus of the cord. *The Lancet* also refers to several curious affection and trophic conditions of the joints in cases of syringomyelia, and SONNENBURG records a peculiar case where, in addition to altered sensory motor and electrical reactions, the head of the left humerus was entirely gone and the finger joints appeared to have enlarged capsules. SONNENBURG thinks that too little attention has heretofore been paid to several symptoms of syringomyelia, among which are:—paresis, diminution of the reflexes and other disturbances of the larynx which interfere rather with phonation than with respiration; unilateral recurrent palsy is more common than unilateral postural palsy; diminution of the scope of pain and the uterine sensibility frequently transitory only; of the ocular apparatus stimulating posterior spinal sclerosis and sometimes a peculiar change in the pressure sense where cutaneous appreciation of pressure is so greatly impaired or abolished that if the pressure sense is tested in the ordinary way no defect is noticed. SONNENBURG, on the other hand, referring to what syringomyelia is a neurological entity, declares that instead of being a disease it is merely a condition which may be present in various diseases of which leprosy is certainly one of the worst forms.

Early diagnosis and treatment of Whooping Cough.

M. VIGNOL thinks that so special signs exist for the early diagnosis of whooping cough. He points out that after a run of three days catarrh there sets in a peculiar, spasmodic, vibrating, piercing, persistent and irritating, but not acquisitive cough, without expectoration and more frequent at night. It is a purely nervous cough which lasts from 7 to 20 or 30 days, after which the whooping cough itself sets in with its characteristic expectorations. Though it is disfigureable, enervating and infectious, and nothing can be done to check it in the beginning, during the convulsive stage, whooping cough in itself does not kill a child. Languor, but the danger lies in pulmonary complications, which should be carefully watched for and guarded against. The rational treatment of whooping cough consists in amelioration of the general condition and is not particularly directed to the hyperaesthesia of the larynx, pharynx or nose. He advocates placing camphorated naphthalene under the child's pillow, or a napkin saturated with a concentrated alcoholic solution of carbolic acid under the bed every night, or better still to put the child to bed in bed clothes freshly fumigated with burning sulphur. He finds that 10 drops *ter die* of a mixture of twenty parts of tincture of belladonna with ten parts of extract of acacia root is fairly well tolerated and gives grand results, but he prefers giving his patients from a teaspoonful to a dessertspoonful three times daily of the following:—

Potassii bromidi 3jss, extract Star-anise 3ss, syrup 3j, which he maintains assists nutrition, alleviates the asphyctic stage of laryngeal convulsions, and diminishes both the vomiting and the number and duration of the fits of coughing.

Bruit de Diabie.

VERSTRAETEN'S researches by auscultation show that while the heart sounds can be confused through the liver substance, the heart murmurs cannot but in certain stomach ailments in which there are hemorrhages a systolic arterial murmur can be heard a trifle to the left of the middle line, and in some anemia, especially of women with chronic stomach disease, diarrhoea, phthisis—a marked venous murmur (*bruit de diabie*), which is present in the epigastrium, is heard midway between the ensiform cartilage and the navel (0.5 to 1 c.m. to right of middle line) as a continuous, blowing, wavy and often musical murmur, which is influenced by respiration and the heart's action, but is inconstant, sometimes difficult to make out, is accentuated by a quickening of the blood stream, and disappears on pressing down over the site of the vena cava.

Scleroderma an easily curable Disease.

BLISS believes that scleroderma is easily curable by persistent massage and mild facials, provided the patient and the physician were sufficiently patient, because the cure necessarily takes long before the skin becomes quite normal. He reports four cases by the method, one of them a man of 59 years of age whom he exhibited to the Wieser Medical-society Society, and in whom the sclerodermic affection, after enveloping the entire thorax, ran backwards over the scapula, taking a forward dive over the symphysis in a line caused by the pressure of a truss. Referring to this as well as to his other cases, BLISS points out that patients excited or in a nervous state often induce a scleroderma, which, unfortunately, runs, until very lately, straight under the heading of incurable diseases.

Factors producing Anæmia in Diseases of the Respiratory Passages.

CHABOY states that some of these factors are:—

- (1). Diminution of the calibre of the passages through which the air passes.
- (2). Diminution of the surface for the absorption of air, and trouble in the lesser circulation.
- (3). Fever.
- (4). Growths (cancers, &c.) in the respiratory tract.
- (5). Hemorrhages in the respiratory passages.
- (6). Pathological secretion of the respiratory mucous membrane.
- (7). Troubles set up in the pulmonary apparatus by diseases of the nose.

SURGERY.

Making and Closing "Incisions" in Abdominal Surgery.

DR. J. B. HOLMES thinks that if more attention were paid to the details required for results free from sequelæ and a trifle less "quick time in operation" than usually obtains with many surgeons, patients would seldom require a second operation for cure and would run less risk of becoming sufferers for life. His advice to the abdominal surgeon is valuable indeed, and may be briefly summarised: (1) After removing his nails from morning let the operating surgeon scrub them and his hands several times with a brush, green soap and alcohol. When thoroughly scrubbed, wash well in a hot one per mille bichloride solution, and lastly in hot sterilised water. (2) Instruments and towels should be thoroughly boiled, while pads, sponges, sutures, &c., must be perfectly aseptic. (3). Give patient a good bath all over; rub abdomen well over with turpentine, so as to liquefy any fatty deposits in the skin and then scrub well with tincture of green soap; mop dry, remove remaining fat with ether, after which wash with bichloride (1 in 1000) solution and then cover the abdomen with a wet bichloride towel (1 to 1,000): pay particular attention to properly cleansing the umbilicus. (4). Though long incisions are to be avoided if possible, there is more danger in too short incisions, and the opening should be just big enough to do the work with ease. (5). Make a clean incision with one sweep of a sharp knife, and when possible, directly in the linea alba, so as to protect against a tendency to post-operative "briths." (6) Before opening the peritoneum carefully control all hæmorrhages preferably by 1:0 sponges, ligatures being necessary; make those of the small vessels cut them short, and if pressure forceps are required, do not make them on for more than three minutes.

(7) Now make the peritoneum, with a mesh-needle, clip it with a scalpel, insert the finger into the abdomen as a guide, and slipping in the knee-bent scissor enlarge the incision in one or both directions, as required. (8) Having completed the necessary internal work, stop hæmorrhages, remove blood clots, and after thoroughly cleansing the wound bring the edges into proper apposition, so as to guard against uneven retraction of the fascia, suture with silk worm gut, the needle being passed through the skin about 0.25 inch from the edges of the wound, and after all the stitches are passed, bring the ends together and apply gentle traction before tying the knots. (9). If for any reason buried sutures are required, kangaroo tendon is preferable to any other suture as it is most rapidly assimilated and causes the least irritation. (10) After the sutures have been applied, the incision is dressed with iodoform, over which is placed a compress of sterilised gauze secured by a pad of bichloride cotton; and the whole held in place by 3 or 4 lightly applied strips of adhesive plaster of 2 inches width; a soft flannel binder is wrapped round the patient, who is then put to bed. The sutures may be removed in from 6 to 9 days.

Chronic Inflammation of the Seminal Vesicles.

DR. GARDNER W. ALLEN, believing that the various inflammations of the vesiculi seminales are analogous to salpingitis, points out that acute inflammation is almost always of gonorrhœal origin, and rarely advances to suppuration, whereas in the chronic form, which may be the result of the acute or of posterior urethral catarrh, consequent on prostatic congestion due to prolonged and repeated sexual excitement, there may be urethral discharge with shreds in the urine, vesical irritability and frequent micturition, urine containing shreds and clumps of blood and pus, disturbed sexual function with deficient erectile power and carnal desire, frequent emissions, spermatorrhœa, hæmorrhoids, vesical discharge from mæstrus at stool, spermatic colic, burning in perineum and urethra, and the various local nervous and mental symptoms peculiar to sexual neurasthenia. Unless indicated by special symptoms, internal medication is unnecessary, and the treatment consists of once in four days (for two or three months) stripping the vesicles by passing the forefinger into the rectum high enough to reach the free end of the vesicle and removing the abnormal secretions by firmly (but gently and carefully) pressing the tip of finger forwards and drawing the finger out without relaxing the pressure, or the obstructions may be dislodged by GOULEY's method of passing a sound into the bladder and pressing the vesicles against it. As too active manipulation is likely to bring on an acute exacerbation, a good deal of judgment is required to avoid over-doing.

Rachitic Deformities: Their Treatment.

ACCORDING to the observations of DR. WILLIAMS, curvature of the femur unless retarding locomotion does not require operation and though out-bowing of the legs (*ipes* or accompanied by *ankles*) before the bones are solidified, is easily corrected by mechanical measures, still forcible straightening over a solid femur is often desirable, even at the risk of causing a simple or a compound fracture; but in adults or in large children osteotomy is advisable, when the out-bowing is extreme. For anterior curvature manual fracture over a hard femur, with planing of osseous is advisable; but ap-
 plying a wire for osteotomy, see commentary as even a wire fracture may after the simple operation can be filled up by nature, while for both out-knee and in-knee osteotomy above the middle of the femur is effective, safe and speedy.

Skin Grafting.

After carefully washing the healthy granulations and the part furnishing the grafts with bichloride solution of 1 to 5,000 and 1 to 1,000 strengths respectively, W. H. MARCY describes best with distilled water. Then pressing the open surface of the skin so as to bulge the integument, he cuts off grafts of the required size and thickness. Lifting these grafts from off the blades of the scissors with a fine pair of tweezers he places them, out surface down, on the granulations to which he straps them with thin strips of adhesive plaster placed basket-wise and encloses the whole with one or two turns of a light bandage. The plaster may be removed in 10 hours when the grafts will be found to have cohered so closely to the granulations that no discharge can lift them off, and good results *always* follow this procedure.

Persistent Urethral Discharges due to Seminal Vesiculitis.

DR. EDGERS FULLER notes that about one-third of the cases are tubercular where seminal vesiculitis causes chronic urethral discharges, wherefore it is important to differentiate between the simple inflammatory and the tubercular cases. In the former, which may require from a month to a year for treatment, the prognosis is usually good, though the parts are tender, indurated and distended. The treatment consists in once a week stripping the vesicles and squeezing out their inflammatory contents into the urethra by means of the forefinger passed into the rectum. In the tubercular cases, many of which become quiescent under hygiene and internal medication, the tenderness is less and the induration more than in simple inflammations; but internal medication is chiefly necessary, as the parts resent the manipulations above mentioned by becoming more tender and indurated, thus aggravating the urethral symptoms.

—:—

OBSTETRICS AND GYNECOLOGY.**The Decline of the Pessary.**

FURCH found it safer and easier to perform a laparotomy than to apply an accurately fitting pessary, which latter, though it heals palliatively, injures definitely by *distending* the fornix vagina so enormously that within a few hours or at most a few days after the withdrawal of the pessary the uterus falls back into its abnormal position. No eminent gynecologist now-a-days invents a pessary or advocates its use; and J. G. BLAKE, in whose footsteps hundreds are now following, writes strongly in favor of *narrowing* the vagina, dilating and curetting the cervix and uterus and shortening the round ligaments; but sees no advantage whatever in neutral fixation of the uterus and utterly dispensing with pessaries as a nuisance declares strongly in favor of dilating, curetting which alone or combined, as occasion may need, are in his mind the only true solutions up to date of the vexed problem of uterine displacements.

Treatment of Uterine Hemorrhage during the two last months of Pregnancy.

DR. W. J. BARTLY thinks that hemorrhage at this period results from (1) disease, (2) premature separation of the placenta, and (3) wounded accidents. The first of these will require special and special treatment in accordance to the disease with which it is associated. In the second case, where the hemorrhage is severe, the patient will resist to admit two fingers when the bleeding can be controlled by inducing parturition; but this cannot be done if the internal os will not admit 2 fingers or when labor is already too far

advanced to permit of version. *Fracturing* the os is necessary. Accidental hemorrhage may be controlled: (1) plugging the vagina in external hemorrhage. (2) With a small os and weak or absent labor pains keep the os *intact* as long as possible. (3) If labor be well advanced rupture the membranes and deliver as soon as you possibly can, and (4) in internal concealed bleeding or in cases, sometimes, of external hemorrhage, which cannot otherwise be readily controlled, employ *accouchement forcé* or Ponsé's operation; but in all cases use very little force and *never* hurry.

Imperforate Hymen; Imperforate Os Uteri; Hematometra; Hysterectomy.

Drs. MORTON and MURPHY report a case of a woman, aged 42 and married 25 years, who had never menstruated. Her womb seems to have hibernated till its owner reached the age when catamenia cease and then only began its duties with such gusto that she began to *swell* in the abdomen, lose flesh and suffer a great deal of pain. The hymen was imperforate, forming a cul-de-sac three inches deep and the os uteri was completely closed. Abdominal section revealed a huge tumour covered with a thick layer of grayish colored peritoneum and containing, besides 10 ounces of brown serum, a large mass of organized blood clot. This was removed and the womb, which was *shelled* out of the broad ligament had to be extirpated with its appendage. The broad ligament was sutured to the abdominal wound and the whole properly dressed. The patient made an uninterruptedly good recovery; but four months later returned to the infirmary in great pain with a very much distended abdomen from which 60 ounces of organized blood-clot had to be cleared out and she again recovered. A few weeks later she swelled up enormously for the third time and the cloatrix (of the abdominal wound) bursting a brown serous fluid escaped for some days, and she died after refusing all treatment. A *post-mortem* examination was refused.

An Obstetrical Problem.

In reply to the question as to what manner of man *physically* the obstetrician should be, DIONIS declared that he should have no defect that would shock the eye of a lady, and while being neither too young nor too old, he possess a soft voice, a gentle hand and a frame capable of withstanding fatigue. Major FRANCE declares in favor of *main de fer en gant de velours*; but other writers think that in order to not excite the jealousy of the *accoucheur* should be ugly, untidy in dress, dirty in person with a long beard and unkempt hair, gruff of voice and unattractive in manner or appearance. These practices obtained in the time of MAURICEAU, who inveighed bitterly against them as militating against common sense which maintained that it was a mistake for a surgeon of whom females were afraid by nature to make himself more feared by such expedients; for nature demands "cleanliness, cleanliness and yet again cleanliness," and the French have it that the *accoucheur* whose "finger nails are in mourning is a murderer," and modern successful gynecology declares in favor of cleanliness, tidiness, frequent ablutions, soft manners and strict attention to the petty details of parlance, habits and despatch in work.

Ectopic Pregnancy at the Utero-Tubal Junction.

A MEXICANA, aged 30 and mother of ten children, complaining of severe expulsive uterine pains and a moderate discharge of blood per vaginam, was examined by Drs. CHACON and FERRONER who discovered a tumour of the size of a small

ment attached to the left of and apparently continuous with the uterus. While her temperature ranged between 101° and 102° F. and there were other symptoms of extra-uterine pregnancy. On opening the abdomen the hæmatoma was found continuous with the left border of the uterus and underneath the Fallopian tube, while the tissues covering it were quite healthy, except at the junction of the womb and tube where they were thinned out to form two prominences each of the size of a small English walnut. After stitching the parietal peritoneum to the uterus and the thicker portion of the walls of the hæmatoma and closing the remainder of the abdominal wound, the thinned portion was ruptured by moderate pressure and the opening enlarged to give access to the sac, which was evacuated of three-fourths of its contents of clot, filled with iodoform gauze and dressed. The patient made an uneventful recovery and has menstruated regularly since operation.

Vaginal total Extirpation of the Uterus and Adnexa in Suppurative Disease of the Female Pelvis (Pean-Second Operation.)

PEAN's suggestion of treating suppurative pelvic disease by vaginal extirpation of the womb and its appendages came like a shock to those surgeons, who supported abdominal section and ovarian ablation till he put his theory into proof by on 12th December 1886, performing this operation in a case of endometritis, complicated with salpingitis, pelvic peritonitis and suppurating cysts of the ovaries, together with a large inflamed and painful uterus implicated in the surrounding exudations; but no one cared to follow suit till SECOND successfully performed a similar operation and became enthusiastic over the results obtained. Later on PEAN reported 150 operations with only 0.75 per cent. of mortality; SECOND 103 cases with 10 per cent. deaths; JACOBS 140 cases with a 1.42 per cent. mortality; and DOZEN and LANDAU 77 and 88 operations, respectively, with no deaths. The favorable results obtained justify the contention that by the vaginal method the work of removal is rendered much easier and less dangerous, and a large opening is left which when packed with gauze, makes the best possible drain. The after treatment is far less troublesome than that needed after abdominal section, the surgical shock infinitely less, and recovery quicker, the patient being allowed to sit up in 8 to 10 days, and there being very little trouble in changing the dressing. After the first dressing is removed, the vagina should be irrigated once or twice daily with warm water, and the bowels moved on the third or fourth day.

Some Symptoms which simulate Disease of the Pelvic Organs in Women.

IMPROPER feeding, want of methodical exercise and irregular bathing, according to A. RABAGLIATI, M.A., F.R.C.S., often give rise to the tired, listless fatigued feeling, the headaches and pains in the iliac, lumbar, and ilio-inguinal regions—aching through to the back—that many women complain of the gait appearing to lessen while in a lying position are aggravated by sitting down or moving about, and are much worse during and after the menstrual period. Leucorrhæa, myalgia, ovarian neuralgia, perimyositis, rheumatica perimetritis, B. periostritis, elphoritis and other ovarian and uterine complications accompany these symptoms of apparent disease of the pelvic organs has led to extirpation to the whole of them or some parts of them, or to the employment of pessaries with little or no permanent relief. DR. RABAGLIATI thinks that instead of rushing into operation it is wisest—except of course for salpingitis, cancer, &c.,—to try what can

be done by a liberal diet and proper bathing, followed by the methodical exercises of auto-plesto-myo-kinetics which are calculated to induce a return to health by putting into action the often diseased and pained muscles.

Treatment of Distention of the Fallopian Tubes without Laparotomy and Removal.

WHILE most other surgeons argue in favor of operative interference, DR. F. A. GLASGOW contends that tubal distention is best cured by intra-uterine treatment, and submits that he has cured some twenty cases by the following methods: (1) By gradually packing with gauze without anesthesia. (2) Rapid dilatation of the cervix and packing with gauze after curetting. (3) Dilating by means of antiseptic sterilized elm-bark tents, made of strips of elm-bark just long enough to completely fill the cervix without pressing on the fundus. These tents are kept in an alcoholic solution (1 to 4000) of bichloride of mercury till required for use, when they may be dipped into glycerine or water just before introduction.

—:O:—

PHYSIOLOGY, PATHOLOGY AND BACTERIOLOGY.

Nerve Supply of the Ovary.

DEVORA, in order to ascertain the distribution of the nerve fibres up to their ends in the ovary, used GOLGI's staining method and furnishes the results of his study in the proceedings of the Academy of Medicine of Belgium. He made use of several different animals—the dog, cat, rat, mouse, guinea pig, turtle and calf. He describes a network of nerves, which accompany the arteries, arterioles, veins and venules; but found no vasomotor system along the capillaries nor, in general, at points where there is no unstriated muscular fibre; neither did he find any ganglion cells. Besides the network just mentioned, there exists in the ovarian stroma, and especially in the cortical zone, a plexus very rich in trunks and fibres interlacing in every direction. This plexus penetrates into the albuginea and some parts reach the base of the germinal epithelium, outlining the young follicles and forming a compact network around the adult follicles. The author found fibrillæ even in the granular layer, where they terminate in cylindrical swellings, but he was not able to prove these to be end-organs.—*N. Y. Med. Jour.*

Influence of Fasting on Muscular Force.

AN Italian physician, SIGNOR MANEA, has recently investigated the influence of fasting for periods of twenty-four and of thirty-six hours on his muscular power, testing this both by voluntary efforts of, and by the application of an electrical current, to, the muscles of his forearm. The conclusion at which he has arrived is that fasting within the above limits has no influence on the muscular power. The deviations after longer periods observed by other investigators he thinks are attributable to the effects of the fasting on the nervous system, circulation, and respiration. SIGNOR MANEA distinguishes two stages in fasting: one in which a kind of compensation of the injurious effects of fasting is effected through the agency of the nervous system, and a second in which there is deranged compensation, with disturbances of the several organs strongly marked, accompanied by loss of weight and abundant excretion of nitrogen in the urine, after which death occurs. The great powers of resistance possessed by the muscles in regard to their force are, he thinks, due to the glycogen and sugar in the blood, which do not materially alter in quantity even after prolonged abstinence.—*Lancet.*

The Kidneys in Pneumonia.

In 150 cases of pneumonia, with 45 deaths, REICHER examined the kidneys in 40 cases, 24 men and 6 women. In these cases no microscopical changes were evident. Microscopically, however, typical changes could be demonstrated. The changes were embraced under the following heads: (1) The changes involved only the cortex. (2) The changes implicated the secretory parenchyma, leaving the interstitial tissue intact. (3) Exudates were found in the capsules of the glomeruli. In 5 cases, the changes were caryolitic and necrotic, whereas, in the remaining cases, the changes implicated the protoplasm of the cells, which were swollen and broken down. These changes were not of an inflammatory but of a degenerative nature. They can be referred, as in cholera, typhoid fever, etc., to toxic, i.e., bacteriæ products. The so-called febrile albuminuria in pneumonia is the clinical symptom of these degenerative renal changes, although this symptom may be absent notwithstanding the changes. In the renal parenchyma, pneumococci were demonstrable and accepted as the factors of the degeneration. The pneumococci could be cultivated on agar, and the cultures infected animals. The writer concludes that the presence of albumin, and even casts in the urine of pneumonic patients, is not a signum mali ominis, inasmuch as it is dependent on a degenerative process capable of reparation.—*American Practitioner*.

Transmissibility of Cylindrical Epithelioma.

H. MORAU'S experiments on white mice established the fact that tumours of the above kind can be engrafted on animals of the same species. That heredity plays an important part in the development of cylindrical epithelioma while pregnancy hastens their evolution. In the absence of ulcers they contain no bacteria, but when they do ulcerate, all the micro-organisms of suppuration are present. They may become generalised, and this generalisation is accelerated by injury of any kind; but in proportion as they develop in new organisms they lose virulence and inoculability.

Absorption of Bacteria into Recent Wounds.

SCHIMMELBUSCH finds that no matter how powerful the disinfectant, neither good nor even favorable results can be obtained by disinfecting wounds infected by disease germs, as the micro-organisms pass too rapidly from the wound into the body juices. NIESSEN showed that anthrax spores were demonstrable in the lymph glands in from 30 minutes to 3 hours after infection of a distant part, while five minutes after inoculation sufficed to distribute saprophytes over the entire organism, and fatty emboli containing cinnabar takes scarcely five minutes to reach the heart from the marrow of the bones. PRUNT, who confirms the above statements, adds that resorption is naturally varied, according to the quality of the germs which act as excitants of sepsis; but says that when germs were scattered over wounds that were 24 to 48 hours old, the animal in many cases escaped infection. SCHIMMELBUSCH maintains that poisonous material is not readily absorbed from the superficies or from fascia, as also with burns, old wounds, and cankered sores, in all of which the receptivity disappears probably in consequence of coagulation products, which afford protection. As regards cauterisation, he found that while hot air at 140°C (284°F.) had no effect in two hours. A one-per-cent solution of corrosive sublimate produced perfect disinfection in one second.

PUBLIC AND DOMESTIC HYGIENE AND JURISPRUDENCE.

The Disposal of Garbage in New York.

THE following resolutions, adopted by the Section in Public Health, Legal Medicine, and Medical and Vital Statistics of the New York Academy of Medicine, were approved by the academy on January 3rd.

Whereas, In many cities garbage is disposed of by garbage furnaces within the city limits, without odor, smoke, or nuisance of any kind whatever, as well as at a profit; and,

Whereas, In New York the disposal of garbage by sewers entails a complete loss of \$175,000 per annum, and causes an intolerable nuisance to the dwellers on the neighbouring coast, because of garbage, ashes, and carrion floating ashore, which substances may, by means of garbage furnaces, be transmitted into steam power that would have a value of \$160,000 a year; therefore be it

Resolved, That the present cumbersome, expensive, and insalutary system of collecting, transporting, and disposing of the household garbage of New York should be abolished.

Resolved, That the city be divided into districts, and that the privilege of collecting and disposing of garbage be sold to contractors, held under bonds for the faithful performance of their duty.

Resolved, That it be recommended that coal ashes be collected and stored by householders without swill admixture, as is at present required by law.

Resolved, That odorless garbage furnaces be constructed in each district, as in other cities, and that all garbage be disposed of immediately by incineration therein, while the ashes and junk be disposed of by the contractor as a source of profit.

Resolved, That, inasmuch as at the present time the sanitation of households in New York is under the supervision of the board of health, it be recommended that the collection and disposition of the household garbage be committed to that department and divorced altogether from that of street-cleaning.

Resolved, That this reform is recommended in the interest of public economy, as the present system in vogue is uneconomical and expensive; besides, by establishing modern scientific discoveries and principles, what is now a matter of great expense may be made a source of revenue to the city.—*N. Y. Med. Jour.*

The Sterilisation of Drinking Water.

A VERY simple and efficient method of sterilisation of water is highly recommended by M. MEILLER, Chemist-in-Chief of the Academy of Medicine. Four drops of the tincture of iodine of the French Codex sterilises in a few minutes one litre of spring water, all pathogenic micro-organisms being destroyed. For ordinary household use M. MEILLER states that the best method of sterilising water is to prepare with it an infusion of tea, limes, or hops; but the iodine method may, he says, be advantageously employed by travellers.

How to Get Warm.

It may not be generally known that when exposed to severe cold, a feeling of warmth is readily created by repeatedly filling the lungs to their utmost extent in the following manner: Throw the shoulders well back and hold the head well up; inflate the lungs slowly, the air entering entirely through the nose. When the lungs are completely filled, hold the breath for ten seconds or longer, and then expel it quickly through the mouth. After repeating the exercise while one is chilly, a feeling of warmth will be felt over the entire body, even in the feet and hands.

How to Cook Corn Meal.

Take of good, best corn meal, one quart, fresh and rather dry. Boil in water. If salt is desired, add a very little. When the corn meal is cooked, add a very little of the corn meal, heap up in a dripping pan which has been previously oiled and baked, and bake brown in a hot oven.

Corn Meal and Fig Pudding.

Beat together a scant cup of best sifted corn meal with a cupful of molasses, and stir the mixture gradually into a quart of boiling milk. Cook ten or twelve minutes, or until well thickened, then set aside to cool. Add a cupful of finely chopped figs, one and two thirds cups of cold milk, part cream if it can be afforded, and when the mixture is cool, add two well-beaten eggs. Pour into a pudding dish and bake in a moderate, steady oven for three or more hours; the longer the better. When the pudding has baked an hour, pour over it a cupful of cold milk. Do not stir the pudding but allow the milk to soak in gradually. A pint of finely sliced or chopped sweet apples may be used in place of figs for variety, or if preferred, both may be omitted.

The Physical Signs of Virginity.

"A VIRGIN" so says the dictionary "is a woman who has had no carnal knowledge of a man," and tradition hath it that while the presence of the hymen is the sign of virginity and the test of the virtue of an unmarried woman, its laceration or absence is the proof of her deforation, but there are numberless instances where sexual intercourse has been completed and conception taken place without rupture of the hymen, and others whose chastity is beyond question are either devoid of hymen altogether or have one whose orifice is exceedingly large. Though in the majority of instances it is possible to detect a virgin by vaginal examination, still the proportion of virgins is very small in whom the hymen is so well formed and its orifice so small as to warrant a dogmatic statement of virginity, and we quite agree with our contemporary the *British Medical Journal* in his assertion. "There is then no one physical sign from which a medical man can assert of any woman that she is *virgo intacta*, an untouched virgin," and unjust though in some cases it may be to side with her in a prosecution for rape we are constrained to accept the woman's statement that she has been actually ravished in that instance if other circumstances point to her truthfulness and chastity.

Definition of Insanity.

EGGIS in his new manual on "Mental Medicine," translated by H. M. BAXTER, and issued by the American Journal of Insanity press, while referring with feeling to the definition of insanity of *ESQUIRAL*, demonstrates some of its unreliable features, and gives the following as his own: "Insanity is a special disease and form of alienation characterized by the accidental, unconscious and more or less permanent disturbances of the reason."

THERAPEUTICS AND PHARMACOLOGY.

Potassium Nitrate in the Treatment of Phlegmasia Alba Dolens.

DR. C. H. HOFFMAN reports three interesting cases:—The first a primipara, 28, whose perineum and perineum were extensively lacerated during instrumental delivery, complained on the 15th day of pain and heaviness in left leg which, three days later developed well marked phlegmasia. Temperature rose to 102°F., pulse 120, and respirations 20, and there seemed great danger of gangrene or rupture; the leg being so painful and swollen. The leg being placed at a very obtuse angle on

a feather pillow after being wrapped in cotton, she was given 5 grains of nitrate of potassium every hour. The temperature fell to 98°, the pulse to 80, and respirations 18, and the swelling was reduced to less than one-half in 20 hours. Two days later the limb was well. The second case, a multipara aged 32, exhibited somewhat similar symptoms, but rather more aggravated with good deal of abdominal tenderness and tympany, so she was given 5 grains of nitrate every half hour for eight hours, after which the dose was reduced to 5 grains every hour. In 24 hours the swelling and pain had disappeared; but careless movement by her attendants brought on a relapse which was again controlled by the nitrate, and she made a rapid recovery. The third case, a multipara aged 30, had a normal labor, but on the third day she had an abundant flow of milk, which was checked by massage and laxatives, and on the sixth day phlegmasia developed in the right leg. Here again the nitrate and the wrapping and placing of the limb at an obtuse angle on a feather pillow for 18 hours rapidly reduced the swelling and the temperature—the latter falling to 97.8°F.

The treatment of Tuberculosis with yeast Nuclein.

THE conclusions drawn by DR. VICTOR C. VAUGHAN, M.D., F.R.C., Professor of Hygiene in the University of Michigan after an extended trial of yeast-nuclein in the treatment of pulmonary tuberculosis are:—

1. That in cases where cavities have begun to form in the lungs, nucleic acid from yeast will not produce a cure.
2. So long as secondary infection with pyogenic germs has not occurred, although the tuberculosis may be of long standing and the extent of tissue involved may be great, the remedy if used properly, will retard (not cure or arrest) the progress of the disease.
3. In initial cases, where there is no secondary infection, and when the area involved is small and the patient has some amount of resistance, the proper employment of the remedy may produce at least a temporary cure.
4. In a few cases of urinary tuberculosis the results have been remarkably satisfactory.

He further remarks that it is highly essential to the successful treating of the disease that it should be detected as early as possible. Also that nucleic acid, if used to excess, will certainly do harm. It acts "by stimulating the organs that elaborate the polynuclear corpuscles and these may be over-stimulated. Nucleic acid fails to be of service unless these cell-forming organs respond. They may fail to respond on account of lowered vitality, or they may be paralyzed, as it were, by an excessive dose of stimulant."

Treatment of Nocturnal Enuresis.

DR. D. MACALISTER having first examined the patient to see that no surgical aid is required, gives atropine and strychnine in doses gradually increased. Saccharin, instilled into the eyes, may be used to counteract the action of atropine on the iris. The patient is awakened in the middle of the night, and at early morning, for the purpose of emptying the bladder. The medicine is administered at 9 P. M., and no liquids are allowed after 6 P. M. The secret of success in this method of treatment lies in giving the drugs, especially the atropine, to the full limit of tolerance.—*The Practitioner*.

Acute Dysentery.

HYPODERMATIC injection of morphia, 1 or 2 grains (0.02 or 0.016 grammes). Ipecacuanha, 30 grains (2 grammes) of the powder, made into four large pills with 15 to 20 minims (1 to 1.32 grammes) of dilute sulphuric acid. Held in butter so that pills slip down easily and patient does not even taste them. Large doses (30 to 40 grains—2 to 2.60 grammes) of drug must be used, repeated according to effect on patient.—*Universal Med. Jour.*

Correspondence.

AN APPEAL TO INDIA FOR EPSOM COLLEGE.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—Within the last decade the growth of Epsom College as a public school has exceeded the most sanguine expectations of its friends.

It occupies a firm and growing position in public favor, whilst the successes of its pupils at the universities and colleges have so filled up the school that the accommodation is no longer sufficient to meet the demand for admission.

This onward progress, however, is threatened with interruption from want of funds. We, who with our colleagues of the governing body, take a deep interest in the welfare of this much needed school, would earnestly appeal to every member of the profession to contribute to the support of an institution which does so much for medical men; for without such aid it becomes only too probable that it will be prevented from attaining the high position at which it justly aims, and to which it is certainly now tending.

(Of the £6,000 annual outlay for the pensioners and foundation scholars, it is to be noted that at present barely one-third is contributed by the medical profession. We cannot help thinking that this has only to be made known to be remedied.)

We wish to point out that no school of its size offers such remarkable advantages to those who intend to enter the learned professions, especially that of medicine, or who may desire to follow scientific pursuits. Numbers are applying for admission, but the school is now full. Great benefit to the foundationers as well as to the other boys would result from extension of the school buildings, but this is impossible without a further increase of pecuniary support.

It must be remembered that there is but very little to depend upon in the way of dividends. To enable the governing body to carry on the school, which is now so thoroughly established on a sound educational basis, the substantial aid of those most interested in it is required. We feel therefore that contributions however small—and we appeal to every medical man in the United Kingdom and India—would strengthen the position and prove that not only is the school a subject of interest, but that confidence is reposed in the endeavour of the governing body to benefit the members of the medical profession.

Subscriptions may be paid to the Treasurer, DR. HOLMAN, 26 Gloucester Place, Portman Square, London, W., or the Secretary at the office, 37 Soho Square, London, W.

Yours &c., J. FAYRE, M.D., K.C.S.I., *Chairman of Council.*

A. HOLMAN, M.D., *Treasurer.*

CHOLERA AND ITS TREATMENT.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—During the recent epidemic of cholera in Ahmedabad, I had a total mortality of only 21 out of 100 patients, but it is probable that the mortality would have been smaller still had the patients strictly followed the directions for treatment, as of two cases in this city and five in Poona,

who were similarly treated, all recovered. I used the following powders and mixture:—

R. Bismuthi subnitratæ grs. xxx, amoniacæ carbonatis grs. ix, sodæ bicarbonatis ℥. Div. pulvis i℥. One every hour, in half a wineglassful of water.

R. Potassæ chloratis ℥i, spiritus ammoniæ aromatici ℥iiss, liquor sodæ chloratis ℥i, tincturæ cinchonæ comp. ℥i, spiritus chloroformi ℥i, tincturæ zingiberis ℥i, aqua menthae piperitæ ad. ℥iij. Fiat Mist. ℥i every hour, and alternated the mixture and powder every hour in every cholera case. Though I do not claim any specific action for these remedies, still they proved wonderfully successful in my cholera cases, as the powder checked the vomiting which recurred on taking the mixture, which relieved tympanitis and controlled the purging. These medicines were persevered in till recovery took place. As adjuncts were given brandy, ice and soda and congee; but opiates and solid food were strongly interdicted, while water was restricted to very small quantities at a time.

Yours, &c., J. B. BAMNOLKAR, C. M. S.,

Medical Practitioner.

THE I. M. A. MEMORIALS ON CIVIL ASSISTANT SURGEONS AND HOSPITAL ASSISTANTS.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—Please convey my heart-felt thanks to the President and Council of the Indian Medical Association, for having, so soon after the organisation of the Association, taken up the cause of the ill-paid Civil Hospital Assistants throughout the Empire, and submitted a memorial to the Surgeon-General with the Government of India, fully representing their grievances and suggesting needful reforms. I earnestly hope that the Council will continue to evince the same kind of interest on our behalf.

Yours, &c., P. S. J., *Hospital Assistant.*

KULITALAI, 13th February 1895.

II

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—It gave me much pleasure to read the representations on the grievances of Civil Assistant Surgeons made by the Indian Medical Association to the Surgeon-General to the Government of India, published in the last issue of the *Record*. A more concise, definitely to the point and properly couched representation, could certainly not have been made. I know not in what terms to express our feelings of gratitude, and in what terms to offer our sincerest and best thanks to you, who, as Editor of the *Indian Medical Record*, did from the very beginning open up your columns for ventilating the subject, and who, as Secretary to the said Association, has taken so much trouble in bringing it to so promising an issue.

Would that a time may not be far off when we, the brother Assistant Surgeons of all the three presidencies, might join in expressing our feelings of gratitude to the founder of and Secretary to the much-needed medical Association in India in a more substantial way.

Yours, &c. PURNA CHANDRA DASH GUPTA, L. M. S.,

Assistant Surgeon.

KISHORGURGE, 5th February 1895.

(We have received numerous letters of thanks from Assistant Surgeons and Hospital Assistants throughout India and Burma, but we will without publishing any others, lay them before the Council.—ED., I. M. A.)

THE INDIAN MEDICAL RECORD.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

Sir,—I am very glad to see that the Indian Medical Record has taken up the cause of Civil Assistant Surgeons and Civil Hospital Assistants. I should be glad if you could take up the cause of the Military Hospital Assistants as well, whose no answer has been received to the petition submitted by this class a few years ago. Can you enlighten us as to when the seconding of those in civil employ is to take place; as also when the increase in pay of the military hospital attendants of the Indian Army Hospital Corps is to be awarded, and which they have been patiently and anxiously looking forward for.

Yours, &c., MILITARY HOSPITAL ASSISTANT.

THE BOMBAY MEDICAL COLLEGE PRIZES FOR MILITARY STUDENTS.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

Sir,—I beg to correct the 3rd paragraph in the article headed "the Bombay Medical College and Prizes for Military Pupils" by "Æsculapius Junior" in your issue of the 15th instant.

I was fortunate enough to carry off a prize of books presented for clinical and minor surgery by Dr. MASINA, the tutor in surgery, who gives such a prize each year.

I dare say Dr. HATCH will give his pocket case for clinical surgery this year, and trust one of the junior military pupils will be the lucky recipient.

If the other professors gave a prize each in their special subjects, it would be an encouragement indeed, especially if the competition was open to all students.

I must also state that there are medals and good conduct prizes for the first three out of the four years of our college career.

Yours, &c., JOHN VINCENT JAMES, D. G. M. C.
Assistant Surgeon, I. M. S.

STATION HOSPITAL,
BARRACKPORE, 25th February 1895.

W. M. O'S. PROVIDENT FUND.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

Sir,—In reply to "P. F." allow me as a well-wisher of the Fund (a subscriber since 1893 and up to date) to write a few words on the subject.

Of late there have been many suggestions as to what should be done to keep the Fund alive—it is alive I believe, for the simple reason that the Bank receives our deposits for the Fund without objection.

Surgeon-Captain WADDE will in time make public the position of the Fund, and until he requests members to select another Secretary, I think there is no need of suggestions as to appoint a new Secretary, especially from members who have lost all claim in the management of the Fund, for some of the would-be reformers have failed to remit their subscriptions for some time past.

In 1894 I made two proposals to Surgeon-Captain WADDE.

1. To reduce the subscription to 2 per cent.

2. To allow members who did not join the Fund when they had an opportunity of doing so, to pay the entrance fee of Rs. 10 and 12 months' back subscription. I now put forward these two proposals again for consideration.

In conclusion, with all due regard to "P. F.'s" criticisms, in the event of Surgeon-Captain WADDE resigning the Secretaryship, I would beg to suggest that Surgeon-Captain HODGKINS be requested to kindly undertake the office.

Yours, &c., GEORGE DEAN CROFT,
Assistant Surgeon.

A PRESCRIPTION FOR DYSENTERY.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

Sir,—The following prescription has been used in the Mandoli Regimental Hospital at Bhurtpore by Surgeon R. K. TANDAN, M.B., C.M., Edin, Chief Medical Officer, for a considerable time, in many cases of acute dysentery, and I have never seen it fail:—Quinine Sulph. grs. ii, Pink Ipecac Rad. grs. v, Ammon Chlorid. grs. x, Tincture Opilii ℥i, xii, Aque ℥i to be given every four hours.

Yours, &c., SURM DEO DAS VERMA, C.M.S.,
Mandoli Regiment, Bhurtpore.
BHURTPORE: 6th November 1894.

REVIEWS.

THE ASEPTIC TREATMENT OF WOUNDS. By Dr. Schlimmelschuss, Privat docent and Assistant Surgeon in Professor VON BERGMANN'S University Clinic at Berlin. Translated from the 2nd German Edition by ALFRED THEODORE RAKE, M.B., B.S. (Lond.) F.R.C.S. (Eng.). Registrar and Pathologist to the East London Hospital for Children. Formerly Surgical-Registrar to Guy's Hospital. (Published by H. K. Lewis, 186, Gower Street, London, W.C. 1894. Price 5s.)

The contents of the 250 pages of letter-press contained in the work under review are a résumé of the lectures and demonstrations given by Professor VON BERGMANN'S able Assistant, Dr. SCHLIMMELBUSCH during the 40th International Medical Congress, held at Berlin, also scattered articles published in Proceedings and Transactions by Professor VON BERGMANN and his former and present assistants.

This is an age when *cunctæ credendi* prevails to a prodigious extent, and of making many books "there is no end," SOLOMON wisely observed.

"When shall we hear the last of germs and antiseptics?" "Still another book?" are questions that no doubt greet every new work dealing on these subjects that comes the light of day. Dr. SCHLIMMELBUSCH'S late *Addendum* is yet another quota to the immense mass of literature that has already been written and published on bacteriology and antiseptic surgery. These subjects, though old and threadbare, are yet ever new and open up fresh fields for research and experiment to those who care to unravel their secrets.

There is nothing old or "stale" in the work before us. Every chapter is thoroughly written and bears the imprint of originality. Professor VON BERGMANN'S name in connection with any work or undertaking is in itself a sufficient guarantee that the said work is really genuine and sure to be instructive. Such is the case with the monograph on the aseptic treatment of wounds, so ably written by his clever collaborator, Dr. C. SCHLIMMELBUSCH.

The work treats, among others, of such subjects as infection, disinfection, sterilisation, and aseptic principles, as applied to drainage of wounds, sponges, hypodermic syringes, catheters, and fluids for washing and irrigation (by sterilisation). These subjects are all discussed in a masterly way, and convey an immense amount of knowledge, the result of original research and laborious study. The book is a monument to one of the highest and latest advancements in science, and is admirably adapted to the requirements of the most punctilious and exacting bacteriologist, at the same time serving as a guide and a text-book to interpret and make familiar the details of Professor VON BERGMANN'S clinic. The profession are the richer for the acquisition of such a work, and owe a debt of gratitude to Professor VON BERGMANN and his illustrious ally, Dr. C. SCHIMMELBUNCH.

THE ANATOMY OF THE NASAL CAVITY AND ITS ACCESSORY SINUSES; AN ATLAS FOR PRACTITIONERS AND STUDENTS. By Dr. A. Ouedi, Lecturer on Rhinology in the University of Budapest. Translated from the second edition by Dr. CLARK THOMPSON, M.D. Lond., F.R.C.S. Eng., M.R.C.P. (Published by H. K. LEWIS, 136, Gower Street, London, W. C. Price 6s.)

This little anatomical atlas of the nasal cavity and its accessory sinuses is a real boon, not only to practitioners and students, but even to specialists. That it has been appreciated by the profession is evidenced by the fact that it is already in its second edition (having been published only a year ago), and has passed through two Hungarian editions also. Further it has appeared in German, and has been translated into Italian and English. Reviewing the work, we may say *ab ovo*, that it is *excellent* in every detail. The plates, 16 in number, have been faithfully reproduced from nature, by being at first carefully photographed and then engraved from the photo-print, consequently each figure is perfectly true to nature, "and is not produced by combining in one picture, the results of several dissections."

Each engraving is prefaced by an explanatory introduction (considerably enlarged in the present edition) arranged topographically, the various parts emphasized, being lettered and noted in *seriatim*.

These illustrations are engraved on good toned paper and are as *beautiful* as they are accurate. They are so distinct in every *minutiae* of detail, that at a glance one can observe and study the relations and mutual connections of every part with neighbouring organs (e.g., ear and eye, &c.) The thanks and congratulations of the profession are due to Dr. A. Ouedi for the production of such a useful and excellent *opusculum*.

LABORATORY GUIDE FOR THE BACTERIOLOGIST. By Langdon Frothingham, M.D., Assistant in Bacteriology and Veterinary Science, Sheffield Scientific School, Yale University. Illustrated. (Published by W. B. SAUNDERS, 525, Walnut Street, Philadelphia 1895.) Price 75 cents.

The above is a neat, concise *brochure* for use in the bacteriological laboratory. The various items noted, are arranged in topographical order, so as to catch the eye and mind; thereby obviating loss of time and temper by sending the bacteriologist to refer to them with ease and pleasure, doing away with having to search for these methods of manipulating microscopical tissues &c., in larger works on the subject. The little treatise before us forms a capital practical guide to bacteriology. It is divided into 4 parts, viz. (1) Bacteriological technique, (2) Staining methods, of which some 16 are mentioned, (3) Preparations of nutrient media, and (4) Imbedding tissues for cutting sections. There are also noted "a few ways by which the work may be much accelerated—ways known to and practised by many, but not perhaps, all."

Two excellent tinted plates are added, illustrative of various bacilli. Dr. Frothingham's little work will no doubt be welcomed by all workers in bacteriological laboratories, serving as it does, a most useful and practical purpose.

Government Medical Service.

GOVERNMENT OF INDIA.

The tenure of the appt. of Surgn. Maj. Genl. A. F. Blandshaw, C.B., A.M.S., as Principal Med. Offr., Her Majesty's Forces in India, is extended to the 31st March.

Surgn. Lieut.-Col. F. W. Wright, D.S.O., M.B., 8th Regt. of Beng. (Light) Infy., leave (p. a.) for two years.

Surgn. Lieut.-Col. E. Palmer, 8th Beng. Lancers, leave for seven months.

Surgn.-Capt. W. H. W. Elliot, 4th Punjab Infy., extension of leave (p. a.) for four months.

Surgn. Lieut.-Col. Frederic Augustus Smyth, to be Brig.

Surgn. Lieut.-Col., vice Brig.-Surgn. Lieut.-Col. W. B. Hooper, retired, 13th Jan'y.

Surgn.-Maj. P. deH. Haig, 1st (Prince Albert Victor's Own) Regt. of Punjab Cavalry, leave (p. a.) for one year.

BENGAL GOVERNMENT.

Dr. J. L. Hendley, Civil Med. Offr. of Jalpaiguri, (leave for one month).

Surgn.-Capt. A. W. T. Bulst-Sparks to act. as Civil Surgn. of Jalpaiguri, vice Dr. J. L. Hendley.

Asst. Surgn. Hari Charan Sen did superny. duty at the Med. Coll. Hosp., Calcutta, from the 24th Jan'y. to the 31st Feby.

Asst. Surgn. Nidhu Lal Hakkar to have tempy. med. charge of the sub-divn. and Disp'y. at Satkhira, vice Asst. Surgn. Akahoy Kumar Nandi.

Asst. Surgn. Gopal Chunder Mukerjee to do the duties of Mil'y. Asst. Surgn. E. A. DuBois in the Presly. Genl. Hosp. Asst. Surgn. Akahoy Kumar Nandi, of the Satkhira sub-divn. and disp'y. leave for one month.

Asst. Surgn. Omes Chandra Banerjee, leave for three months.

Asst. Surgn. Monindra Lal Mitter, House Physician, 2nd Physician's Ward, Med. Coll. Hosp., to do superny. duty in that institution until further orders.

Asst. Surgn. Jogheswar Mukerjee, an additional Asst. Surgn. in the Chemical Examiner's Dept., is apptd. a House Physician in the 2nd Physician's Ward, Med. Coll. Hosp., vice Asst. Surgn. Monindra Lal Mitter.

Asst. Surgn. Benode Behary Ghosal to do superny. duty in the Med. Coll. Hosp., Calcutta, 13th Feby.

Asst. Surgn. Barola Kanta Roy to do superny. duty in the Med. Coll. Hosp., Calcutta, 15th Feby.

Asst. Surgn. Lolit Mohan Laha to do superny. duty in the Med. Coll. Hosp., Calcutta, 13th Feby.

Asst. Surgn. Bully Chunder Sen, Teacher of Medicine, Campbell Med. School, leave for forty-five days.

Asst. Surgn. Dinno Nath Mitter, first Demonstrator of Anatomy in the Campbell Med. School, to act as teacher of Medicine in that institution in addition to his own duties, vice Asst. Surgn. Bully Chunder Sen.

Asst. Surgn. Kalar Nath Malak to do superny. duty in the Med. Coll. Hosp., Calcutta, 17th Feby.

Asst. Surgn. Jogendra Nath Bose, a Resid. Asst. Surgn. in the Campbell Med. School and Hosp., to act as teacher of Surgery in that institution, vice Asst. Surgn. Zuhiruddin Ahmed.

Asst. Surgn. Zuhiruddin Ahmed, Teacher of Surgery in the Campbell Med. School, leave for three months.

Asst. Surgn. Ganga Gobinda Sarkara, of the sub-divn. and disp'y. at Nator, leave for three months.

Asst. Surgn. Hem Lal Dutt, a superny. at the Med. Coll. Hosp., to have tempy. med. charge of the sub-divn. and disp'y. at Nator, Rajshahi Dist., vice Asst. Surgn. Ganga Gobinda Sarkara.

Asst. Surgn. Ganes Chandra Mitra, a superny. at the Presly. Genl. Hosp., leave for one month.

Asst. Surgn. Narendra Nath Gupta to do superny. work in the Presly. Genl. Hosp. until further orders.

PUNJAB GOVERNMENT.

Priv. leave granted to Brig.-Surgn. Lieut.-Col. G. Manney, Civil Surgn. of Marree, is extended by five days.

Second class Hosp. Asst. Hadda Ali is reinstated in the service of Govt. from 7th Feby.

Asst. Surgn. Jhang Ram, doing genl. duty at Chudaganj, to Rawalpindi for genl. duty, 27th Jan'y.

Hosp. Asst. Natha Singh was apptd. to the Kanpur District Kanpur Dist., 16th Jan'y., relieving Hosp. Asst. Vishnu Ram.

Surgeon-General Macdonald (from the **India Canal** Disp., **Delhi** Dist., **1st Feby.**).

Asst. Surg. Major Macdonald (from the **Massachusetts** Disp., to the **India Canal** Disp., **6th Feby.**).

Hosp. Asst. Barnam Singh, **Jalapaour** Disp., **1st Feby.**, by **Hosp. Asst. Sachet Singh**, doing genl. duty at **Delhi**.

On being relieved of the charge of the **Khewra** Disp., **Shelton** Dist., **Hosp. Asst. Phile Khan** was transferred to the **Patti** Disp., **Lahore** Dist., **80th Jan.**, relieving **Hosp. Asst. Narasingh Das**.

Hosp. Asst. Muhammad Ishaq resumed charge of the **Sachaura** Disp., **Umballa** Dist., **6th Jan.**, relieving **Hosp. Asst. Guranditta**.

Hosp. Asst. Kirpa Ram, **Thaneswar** Disp., **Umballa** Dist., three months' priv. leave, and was relieved on **13th Jan.** by **Hosp. Asst. Guranditta**, transferred from **Sachaura**.

Hosp. Asst. Khula Bakhsh, doing genl. duty at the **Mayo** Hosp., **Lahore**, one month's leave, **28th Dec.**, **1892**.

Hosp. Asst. Khula Bakhsh to do genl. duty at **Amritsar**, **30th Jan.**

Hosp. Asst. Ganesh Das, doing genl. duty at **Delhi**, to the **Sachaura** Disp., **Umballa** Dist., **28th Jan.**

Hosp. Asst. Ghulam Kadir resumed charge of the **Shorkot** Disp., **Jalapaour** Dist., **1st Feb.**, relieving **Hosp. Asst. Bisanda Ram**.

Hosp. Asst. Narasingh Das, from the **Patti** Disp., **Lahore** Dist., to the **Sinawan** Disp., **Muzaffargarh** Dist., **6th Feby.**, relieving **Hosp. Asst. Lachman Das**.

On being relieved of his duties at the **Kanalla** Disp., **Montgomery** Dist., **Hosp. Asst. Sundar Singh** was transferred to **Muzaffargarh** for genl. duty, **3rd Feby.**

Asst. Surg. Khaleh Chand held charge of the duties of **Supdt.** of the **Gujrat Jail** from the **27th** to the **30th Nov.**

MADRAS GOVERNMENT.

Surgn.-Maj. A. J. O'Hara, priv. leave for two months.

Surgn.-Capt. Frank Charles Pereira, M.B., to act as **Dist. Med. and San. Offr.** and **Supdt.** of **Jail**, **Cuddapah**, during the employment of **Surgn.-Maj. A. J. O'Hara** on other duty.

Colonel Ponappa Gnanapathi Gari, L.M.S., to act as **Civil Surgn.**, **Cannanore**, vice **Surgn.-Maj. S. C. Sarkies** on furlough.

Civil Apoth. Saldapet Chandrasakara Mudali, L.M.S., to act as **Asst.** to **Dist. Med. and San. Offr.**, **Mangalore**, vice **C. P. Gnanapathi Gari**.

Second class Asst. Surgn. M. Bowers to be **1st class Asst. Surgn.** from **10th Feby.**

Surgn. Lieut.-Col. J. A. Laiding, I. M. S., extension of leave (p.a.) for six months.

Brig.-Surgn. Lieut.-Col. J. Smith, I. M. S., **29th Madras Infy.**, leave (m.c.) for three months in extension.

Surgn. Lieut.-Col. H. Allison, M.D., I. M. S., **Profr.** of **Anatomy**, **Med. Coll. Madras**, leave (p.a.) for one year.

Surgn.-Lieuts. Robert Henry Elliot, M.B., B.S. **Lond.**, **R.C.S. Eng.**, **Robert King Mitter**, M.B., and **Wilfred Ernest Arbuthnot Armstrong**, to be **Surgn.-Capt.**, **30th Jan.**

Cent. Asst. Surgn. and **Hon. Surgn.-Capt. J. I. Laffrey**, I. M. S., **Madras**, is permitted to retire from the service, **12th Jan.**

BOMBAY GOVERNMENT.

Surgn.-Capt. J. G. Hojel, I. M. S., extension of leave for three months.

Asst. Surgn. Abdul Ghani Hakim, L.M.S., has been placed on genl. duty from **26th Jan.**

Asst. Surgn. D. C. ... priv. leave for thirty days, **12th Feb.**

Asst. Surgn. S. C. ... M.D., B.S., on relief by **Brig.-Surgn. Lieut.-Col. C. T. Peters**, M.B., to act as **Civil Surgn.**, **Karwar**.

Asst. Surgn. Venkatesh Balwant Karandikar, B.A., L.M.S., to act as **Civil Surgn.**, **Karwar**, until relieved by **Surgn.-Capt. S. R. Prall**.

Sai Rameshbabai, M.B. (Bruc.), L.B.C.P. & S. (Edin.), to act as **House Surgn.**, **Kanva Hosp.**, vice **Miss Frances K. H. Cassin**, M.D.

CENTRAL PROVINCES GOVERNMENT.

Surgn. Lieut.-Col. D. N. Martin resumed charge of the office of **Civil Surgn.**, **Saugor**, from **Surgn.-Capt. R. C. Macdonald**, **6th Feby.**

Asst. Surgn. E. P. Clements assumed charge of the office of **Civil Surgn.**, **Wardha**, **30th Jan.**

Three months' priv. leave is granted to **Hosp. Asst. Ramlogan Singh** of the **Schokra Branch Disp.**, **Jubbulpore** Dist., **7th March**.

Civil Hosp. Asst. Ram Krishna Lal, doing duty under orders of the **Civil Surgn.**, **Jubbulpore**, is temporarily posted to the **Schokra Branch Disp.**, vice **Civil Hosp. Asst. Ramlogan Singh**.

Civil Hosp. Asst. Harji Rao, doing duty under orders of the **Civil Surgn.**, **Saugor**, is appointed to the **Police Hosp.**, **Saugor**.

First Class Civil Hosp. Asst. Jowra Khan Lal, attached to the **Police Hosp.**, **Saugor**, is permitted to retire from the service.

Civil Hosp. Asst. Bhogoo Lal, doing duty under orders of the **Civil Surgn.**, **Jubbulpore**, is temporarily appointed to the **City Branch Disp.**, **Saugor**, vice **Civil Hosp. Asst. Amir Khan**, directed to do duty at the **Garhakota Pals**.

Civil Hosp. Asst. Vilja Shankar, of the **Jail and Police Hosp.**, **Bilaspur**, is granted three months' priv. leave.

On being relieved by **Civil Hosp. Asst. Abdul Karim**, **Civil Hosp. Asst. Ujagar Perahad**, temporarily attached to the **Deoli Branch Disp.**, **Wardha** Dist., is posted to the **Jail and Police Hosp.**, **Bilaspur**, vice **Civil Hosp. Asst. Vilja Shankar**.

Civil Hosp. Asst. Ram Shal to do duty under orders of the **Civil Surgn.**, **Nagpur**.

N.-W. P. AND OUDH GOVERNMENT.

Asst. Surgn. Gopal Chandra Gupta, in charge of the **Sikandrabad Disp.**, **Bulandshahr** Dist., priv. leave for two months **5th Feby.**

Surgn.-Maj. F. C. Chatterjee, **Civil Surgn.**, **Pilibhit**, priv. leave for two months and twenty-eight days, **1st March**.

Surgn.-Capt. O. Macgregor, **Supdt. Central Prison**, **Agra**, furlough for ten months, **3rd March**.

Surgn.-Capt. J. ... on relief by **Surgn.-Maj. F. C. Chatterjee**, attached to the **Allahabad Dist.**

Surgn.-Capt. S. H. Henderson, **superary. Civil Surgn.**, **Fatehpur**, on relief by **Surgn.-Maj. G. A. Emerson**, attached for duty to the **Central Prison**, **Bareilly**.

Hosp. Asst. Jawant Rao, of the **Amrabad Branch Disp.**, **Bulandshahr** Dist., to the **Sikandrabad Disp.**, vice **Asst. Surgn. Gopal Chandra Gupta**, granted priv. leave.

Asst. Surgn. Subhan Ali, **Lecturer**, **Agra Med. School**, to the charge of the **sadar Disp.** at **Banda**.

Surgn.-Maj. J. Anderson, **Civil Surgn.**, **Bareilly**, to hold visiting med. charge of the **Pilibhit Dist.** in addition, vice **Surgn.-Maj. F. C. Chatterjee**.

BURMA GOVERNMENT.

Dr. H. E. Wells, M.B., is temporarily appointed as an **Uncovenanted Med. Offr.**, and is posted to **Burma**.

The services of **Mily. Asst. Surgn. L. J. Bailey** are placed at the disposal of the **Chief Commr.** of **Burma**.

Dr. F. X. deAttales, **Civil Asst. Surgn.** of the **Imperial List**, having passed the prescribed exam. for advancement, is promoted to the **2nd grade**, **2nd June 1892**.

Hosp. Asst. R. S. Dashmookha left **Ry. Disp.**, **Yamethin**, and assumed charge of the **Civil Disp.**, **Henada**, **31st Jan.**

Second Grade Hosp. Asst. M. N. Jonathan and **Shalk Abdululla** qualified for promotion to the next higher grade on the **29th Oct. 1892**, and are entitled to the pay of the same, with the allowance for English qualification, from **2nd July 1893**.

Third grade Hosp. Asst. T. V. Goriindaraju Mudaller and **C. J. Packiam Pillay** qualified for promotion to the next higher grade on the **29th Oct. 1892**, and are entitled to the pay of the same, with the allowance for English qualification, from **1st July 1893**.

Hosp. Asst. Abdul Wahid left **Police Hosp.**, **Mogaung**, and assumed charge of the **Outpost Hosp.**, **Nanyasin**, **Mogaung sub-div.**, **19th Dec. 1892**.

Hosp. Asst. Khema Ram left **Outpost Hosp.**, **Mohayin**, **Katha Dist.**, and assumed charge of the **Outpost Hosp.**, **Manai**, **Katha Dist.**, **14th Jan.**

Hosp. Asst. K. Perumal Pillay left **Outpost Hosp.**, **Manai**, **Katha Dist.**, and assumed charge of the **Police Hosp.**, **Katha**, **20th Jan.**

Surgn.-Lieut. A. E. Berry, I. M. S., is appointed to be in addition to his med. duties, the **Civil Med. Offr.**, **Falam Chin Hills**, vice **Surgn.-Maj. F. Clements Smith**.

Surgn.-Capt. L. H. Carter made over, and **Surgn.-Capt. J. W. Wolfe**, M.B., assumed charge of the duties of the **Secy.** to the **Impe. Genl.** of **Jail**, with **Civil Med. Administration**, **Burma**, **15th Feb.**

Asst. Surgn. Maung Tsin left **Civil Disp.**, **Bamain**, and assumed charge of the **Civil Disp.**, **Attahmyo**, **Thayemyo** Dist., **5th Feb.**

O. C. C.

Surg. Major Alexander Stephen MacGregor, I. M. S. (Surg.) who is leaving on 15th Jan. 1895.

The Surgeon of Hosp. Asst. Nur. Haid, S. M. D. are disappointed with on account of physical weakness for military service.

Surg. Lieut. W. Selby, to the off. med. charge of the 20th Punjab Regt., vice Surg. Capt. D. T. Lane.

Surg. Lieut. G. M. C. Smith, from the off. med. charge of the 10th Bengal Lancers, to the 51st Punjab Inf., vice Surg. Capt. J. G. Jordan.

Surg. Asst. Kanhaiya Lal to the 2nd grade Hosp. Asst. from the 1st Oct. 1894.

Surg. Capt. W. B. Botes, A. M. S., leave (v.p.a.) for six months.

Surg. Asst. A. A. C. Rafter, I. M. S., passed the higher standard in Hindustani, 7th Jan.

Surg. Lieut. J. D. Alexander, A. M. S., passed the lower standard in Hindustani, 7th Jan.

Surg. Maj. P. A. Weir, I. M. S., and Surg. Capt. H. G. Hathaway, A. M. S., passed the lower standard in Pushtu, 2nd Jan.

ASSAM GOVERNMENT.

Sick leave for three months is granted to Hosp. Asst. Lalit Mohan Sen, in med. charge of No. II Divn, Niehuguan-Manipur Road Circle, 20th Dec. 1894.

Hosp. Asst. Karam Ali Haarak, a superny, at Nowgong, is transferred to Shillong, and appld. a superny. under orders of the Civil Surg., 14th Jan.

Hosp. Asst. Raj Mohan Ganguli, in charge of the Sheila Disp., in the Khasi and Jaintia Hills Dist., is, on return from leave, appld. to the charge of the Jowai sub-divn. in that dist., 26th Jan., vice Hosp. Asst. Nil Kanta Sen, appld. a superny. for duty under orders of the Civil Surg., Shillong, 29th Jan.

Hosp. Asst. Sheikh Amir-Uddin Ahmadi, a superny. in the Goalpara Dist., is transferred to the Garo Hills Dist., and appld. a superny. under orders of the Civil Med. Offr. of that dist., 28th Dec. 1894.

Hosp. Asst. Sheikh Amir-Uddin Ahmadi, a superny. in the Garo Hills Dist., is appld. to the charge of the Dalu Disp., in that dist., 6th Jan.

DOMESTIC OCCURRENCES.

BIRTHS.

BATTERSBY.—On 11th Feb., at Rawalpindi, the wife of Surg. Maj. J. C. Battersby, A. M. S., of a daughter.

CHILDS.—On 11th Feb., at Malabar Hill, the wife of Surg. Capt. L. F. Childs, I. M. S., of a son.

MARRIAGE.

WADDELL-BREWER.—On 10th Jan., at St. Anne's, Highgate, Laurence Austine Waddell, Surg. Maj., Beng. Med. Service, to Amy Louise, eldest daughter of Robert Reeves, Esq.

DEATH.

JACKSON.—On 19th Jan., at Nice, Depy-Surg. Genl. C. J. J. Jackson, H. M. Indian Med. Service (retired), aged 61.

NOTICES TO CORRESPONDENTS.

A. L. M. (Jaipur).—Your matter will be laid before the Association at once and forwarded to the Vice-Chancellor of the Calcutta University.

H. K. S. (Raiganj).—Your interesting letter will appear in an early issue.

J. E. W. (Byond).—Kindly give us the names of as many men as you know who have received the license in question from the Surgeon-General, and send in each list with a temperate statement of facts as to your interview with the Surgeon-General, when due notice will be taken of the matter.

F. K. E. (Rawalpindi).—Please apply to the medical schools which educate Hospital Assistants. The members of the Indian Medical Association will supersede all previous acts. Wait patiently for the Government's reply.

J. E. S. (Bathurst).—Surgeon-General, I have a report of the W. M. O. F. and want to know if we receive it, kindly to publish it.

Dr. M. J. McCall (Kangaroo).—In my letter in your journal of 15th October an Military Hospital Surgeon, please correct as follows: "In consideration of this it was an accepted principle by them to undergo an extra two years' study to qualify for the Sub-Adjutant Surgeons grade."

J. F. P. S.—Let us have the games you take exception to. The document in question will soon be issued.

ACKNOWLEDGMENTS.

THE DANGERS OF AN ACT RESTRICTING THE FREE SALE OF POISONS IN BENGAL.

By GURUN, CAPT. J. F. EVANS, M.R.,

and

ASSISTANT SURGEON CHURN LAL BORA, M.B., F.C.S.

Chemical Examiners to the Government of Bengal.

(Continued from page 180, Vol. VIII.)

VI. ACCIDENTAL POISONING.

The most cursory consideration of any record of cases of accidental poisoning must always produce the conviction that the term is almost a misnomer. It is rare to find an instance of accidental poisoning unassociated either with culpable ignorance or grave neglect. There is an old adage regarding the care of edged tools, and surely such poisons as opium, aconite, nux vomica and arsenic are as dangerous as many edged weapons. Yet, if we are to be guided by our knowledge of actual cases, we must believe that to-day in some humble households in Calcutta a poisonous dose of opium is within the reach of children barely able to walk, a want of parental forethought which is productive of cases of opium poisoning.

Poisons in bunniah's shops.—The shops of the *bunniahs* constitute another danger, for they are the source, whence all classes of the community, both European and native, either directly or indirectly through their servants draw their supplies of spices and condiments.

The *bunniah*, besides selling spices and condiments, is a retail vendor of sago, barley, sugarcandy and indigenous medicines, both mineral and vegetable, together with a few European drugs.

The *barba*, with whom the general community are less concerned, sells fresh vegetable drugs only.

Both *bunniahs* and *badias* are, as a rule, ignorant people, scarcely able to read or write their own language. Their knowledge of the properties or identity of the drugs they sell is very imperfect, and the manner in which the drugs are stored renders their ignorance almost criminal.

In a *bunniah's* shop even the poisonous drugs are generally kept in unlabelled earthen "handles" which may happen to be in close proximity to harmless drugs, spices and condiments.

From memory and practice the *bunniah* is usually able to sell his wares without mistake, but should the position of the pots be changed without his knowledge, most serious accidents may arise. On one occasion a customer was supplied with strong nitric acid in place of spirits of wine, and on another nux vomica bark (*kuashla*) was supplied instead of *weighia antidysenterica* (*kuash*). The latter mistake caused the death of a child.

Mistakes are occasionally made even by competent persons well acquainted with the nature of the drugs they vend. A mixture of iodoquin and strychnia was once supplied at a chemist's shop to a customer in place of iodoquin, and on another occasion the proprietor of a medical hall addicted to the use of opium administered *kuash* by mistake to a patient or administered both a dose of nux vomica

instead of his usual morning dose of opium. In both these instances the mistake was followed by a fatal result.

Quack remedies.—Somewhat similar to the sale of drugs by ignorant *bunniahs* and *badias*, and quite as dangerous is the trade in secret preparations and quack remedies. This class of medicines finds a large and ready market among the poor and ignorant classes of the country, the sale no doubt being assisted by an eloquent, if not truthful, description of their origin and virtues.

Instances are recorded of credulous patients having been induced to believe that medicines brought by them from some of these unscrupulous vendors were obtained as a special favor from the gods. The medicines often contain poisons, and as they are prepared by ignorant persons, the dose is often, if not always, excessive.

Cases of accidental poisoning resulting from the use of quack remedies.—Many instances of poisoning produced by taking quack remedies are on record. Thus in 1880, at Sibesagar, a woman took one of a number of pills sent to her from Calcutta with the recommendation that they were warranted to cure dysmenorrhoea, amenorrhoea, leucorrhoea, menorrhagia and uterine troubles generally. Within half an hour of taking the pill, well marked symptoms of strychnia poisoning were induced. The pill was found to contain strychnia.

In 1882 a sepoy of a native infantry regiment was found to be in possession of some medicinal preparations by means of which, to his own pecuniary benefit, he had been in the habit of supplementing the regular medical treatment of his sick comrades. Some of the men thus treated developed symptoms of irritant poisoning, while others displayed symptoms of mercurial marasmus. On analysis the preparations were found to contain arsenic, antimony and mercury.

During the current year six samples of a stock of medicines which were in considerable request among the poor of Calcutta as cancer cures, etc., were referred to the Chemical Examiner for analysis. Four of them contained arsenic.

Accident from administration of charms and love philters.—Certainly less creditable and possibly more criminal even than the foregoing is the class of cases of so-called accidental poisoning, that we now propose to briefly consider. It arises from the use of charms, love philters and of medicines administered with a view to excite the sexual passions.

Charms and love philters are in common use among the ignorant people of the country, and though for the most part they are harmless preparations of betel and different kinds of root fibre, yet occasionally they are compounded of poisonous drugs such as aconite, arsenic, and datara. As a consequence an undetected and unforeseen fatality occasionally results from their use. Thus in 1884 a man unintentionally poisoned his wife, a young girl only 14 years of age, by giving her a so-called love philter mixed with sugar. The girl disliked her husband, and was in the habit of deserting him. The love philter which contained arsenic was administered by the husband apparently in the honest hope that he might thereby gain his wife's affections.

Allied to the administration of dharms containing arsenic and other drugs is the habitual use of arsenic by certain classes of people in India on account of its supposed aphrodisiac properties.

Introduction of poisonous substances into foodstuffs.—Up to this point we have dealt with accidental poisoning only, in so far as it arises from the use or misuse of poisonous drugs as such; but cases of accidental poisoning also arise from the introduction, for the most part through ignorance, of improper substances into foodstuffs. As an example of this may be cited, the coloring of sweets with poisonous pigments by the ignorant sweetmeat sellers of the country. The pigments discovered to have been used in this way are yellow arsenic, verdigris, SCHEEL'S green, chromate of lead, magenta and other aniline dyes. Cases of this kind are well within the reach of police interference, and it must be said are generally prevented in Calcutta.

Occasionally also a poisonous vegetable substance due to some mistake as to its identity is prepared and eaten as food. The following case occurred in 1893, and is an interesting example of the kind. Some individuals near Dacca made a curry of a tuberous root which they had obtained from a neighbouring jungle and mistaken for "*matia aloo*." After partaking of the curry, "they became intoxicated and vomited, remaining insensible for 6 hours. They then regained their senses." On analysis the tuber and the curry were found to contain a violent irritant and narcotic poison. Neither the tuber nor its active principle have yet been identified.

Cases of this kind are however rare, and present a marked contrast to the majority of instances of so-called accidental poisoning, most of which are at least culpable, if not criminal.

VII. CATTLE POISONING.

A glance at the following table will shew at once the nature of the cattle poisoning which takes place. Its undue prevalence has already been considered.

TABLE IV.

Showing the percentage of Arsenic detection in animal viscera and in substances sent for examination as cattle poisons during ten years ending 1893.

| | 1884 | 1885 | 1886 | 1887 | 1888 |
|--------------------|-------|------|-------|-------|------|
| Animal viscera ... | 100 | 100 | 100 | 100 | 100 |
| Cattle poisons ... | 92.59 | 96.4 | 92.35 | 95.78 | |

| | 1889 | 1890 | 1891 | 1892 | 1893 |
|--------------------|-------|-------|-------|-------|------|
| Animal viscera ... | 100 | 100 | 100 | 100 | 100 |
| Cattle poisons ... | 94.78 | 93.66 | 92.36 | 93.18 | 92.5 |

Poison selected for cattle poisoning.—Practically arsenic is the sole poison employed for the destruction of cattle. It has many advantages over other poisons. It is tasteless, certain in its action, and the dose required is small. Further, the hides of animals poisoned with arsenic are more easily preserved.

The method of administration is as follows:—A small quantity of white arsenic is made into a paste with flour, oil or oil-cake, and then wrapped up in plantain or other leaves and thrown before cattle grazing in a field, or introduced into the manger among the fodder.

The seeds of *Lathyrus teres*, *Lathyrus pratensis*, and yellow cleaster are also used as cattle poisons, though but rarely in Bengal. The seeds of *abrus precatorius* are made into a paste, which is dried and then fashioned into a miniature arrow head about 1 inch long and $\frac{3}{4}$ th of an inch in diameter at the base constituting in this shape the well-known "suil poison." The "suils" thus prepared are forcibly introduced through the skin of the animal to be poisoned. In the Punjab, similar "suils" are prepared with arsenic in place of *abrus precatorius* seeds.

Motive for cattle poisoning.—Though cattle are occasionally poisoned to satisfy a grudge, the more usual object is the possession of the hide. The poisoners are a class of people known as *Chamars*, who in return for their services in skinning cattle are allowed to claim a percentage of the profits derived from the sale of the hides.

The destruction of dumb animals, which at present prevails in India, is not only accompanied with much physical suffering on the part of the animal, but it is also unnecessary. If fresh supplies of poison be cut off, with the gradual exhaustion of the stock of arsenic existing throughout the country, a diminution in this class of crime may confidently be expected. The measures proposed for restricting the supply of arsenic will be dealt with later in detail.

By the consideration of the prevalence and nature of the poisoning in the province of Bengal at the present time, we have shewn the necessity for some measures calculated to bring about a reduction of the present prevalence.

The measure which naturally commends itself, and which has been successful in other countries is that usually described as a restricted and regulated sale of poisons.

Accordingly we now pass to the consideration of the best and most feasible means for restricting and regulating the sale of poisons in Bengal.

C. PROPOSED MEASURES FOR RESTRICTING THE SALE OF POISONS.

As recommendations having the same object in view have frequently been made during the past half century, it would be as well to refer to these first, and then deal with the scheme now proposed.

Accordingly our remarks concerning measures proposed for restricting the sale of poisons are easily arranged into the following three sections:—

1. Previous recommendations and their outcome.
2. Proposition now under discussion.
3. Difficulties attending the introduction and working of such a measure or briefly its *pros and cons*.

1. PREVIOUS RECOMMENDATIONS AND THEIR OUTCOME.

The recommendations.—From the year 1645, when Dr. MOTAT drew the attention of Government to the matter, up to the present time, the recommendations to control the sale of poisons have been numerous and frequent. Some of these will now be reproduced. Thus in 1856 Dr. MOTAT's contention was supported by Dr. CHAVASSA, who then wrote as follows:—

"It certainly appears to be a matter of great importance that the importation or at least the sale of arsenic in India should be regulated by stringent legislative enactment. There is no law in India prohibitory of the sale of poisons."

The experience of medical officers in Madras corroborated that of medical officers in Bengal; for in 1879 the

Surgeon-General and the Chemical Examiner to the Government of Madras submitted the following statement to their Government. The Chemical Examiner in his report states that—

"Arsenic is far more frequently used than any other poison. Attempts at poisoning with other poisons unless accidentally, have probably rarely succeeded. There can be little doubt that in this Presidency, the determined poisoner is pretty sure to make use of some arsenical compound. The destruction of human and animal life by this poison is so considerable that some restriction upon the sale of arsenic is, from the medico-legal point of view, highly desirable."

When forwarding the Chemical Examiner's report, Surgeon-General W. R. CORNISH, F.R.C.S., C.I.E., recorded the following views:—

"In passing on this report to Government, I feel that I should be wanting in my duty, if I did not bring prominently to the notice of Government that the experience of the Chemical Examiner's Department shows most conclusively that the poisons resorted to by the people of India for criminal purposes are mainly common, arsenical preparations or mercurial salts, and that no restriction whatever is placed on the sale of such things in this part of India."

"I have no doubt that if some wholesome restriction was brought to bear on the trade in arsenical and mercurial preparations and in some of the more common organic poisons, the crime of administering poison would be less frequent and more easy of detection than it now is, and I venture to hope that the Government may be prepared to deal with the question, having for its object the restriction of the sale of poison in the Presidency. It is not creditable to our administration in this particular that within the last year, no fewer than three persons in the town of Madras should have been enabled to commit suicide by purchasing at druggists' shops without let or hindrance, quantities of chloral hydrate sufficient to cause death."

The necessity for restricting the indiscriminate and irresponsible sale of poisons, especially arsenic, was frequently dealt with by Dr. WARDEN, the late Chemical Examiner to the Government of Bengal, in his annual reports. The following remarks appeared in the report for 1882 regarding cattle poisoning:—

"Arsenic is the poison generally used. Enormous quantities are found in the parcels of suspected cattle poison sent for examination. In one case one pound of white arsenic was found in two packets. It has been urged that any special legislation to restrict the sale of poisons would be useless, because indigenous vegetable poisons are to be found in every hedge-row. This is a fallacious argument. Because vegetable poisons happen to be common, it does not follow that arsenic is to be picked up in roads and ditches. Arsenic is *par excellence* the poison used for criminal purposes in India. If it is impracticable to restrict the sale of all poisons, the indiscriminate vending of arsenic might be diminished by levying on it a prohibitory tax which could place it beyond the reach of the masses. The legitimate uses of arsenic in this country are not numerous, and for the purposes of certain trades it might be issued duty-free, but under the most stringent restrictions."

Dr. WADDILL, while officiating as Chemical Examiner in 1884 during the absence of Dr. WARDEN, referred to the necessity for legislative action similar to that existing in England in the following terms, which was noticed by Government in an interesting resolution also reproduced:—

"The necessity for the imposition of certain restrictions on the sale of poisons has on more than one occasion been represented and has attracted the attention of the Government. The Lieutenant-Governor in the resolution on the report for 1882-83 said that 'the general question as to the imposition of restriction upon the sale of poisonous drugs demands, and will receive, separate consideration.' But up till this time no steps have been taken in this direction. The restrictions in force in England work without trouble to the authorities there, and it is reasonable to suppose that in India as in England increased difficulty of access would soon render the use of poisonous drugs less frequent."

Government Resolution on Dr. WADDILL'S report:—

"The question of the restriction to be imposed on the sale of poisonous drugs has been more than once under the consideration of the Government. It is beset with many difficulties. Poisonous substances exist in every hedge and garden throughout the country, and in the present state of society in Bengal it seems quite impossible that the sale of poisons generally can be effectually controlled. What is more important is to check the ignorant compounding of English drugs and medicines. With this object provision has been made in the Bengal Municipal Act 1884 for the registration of shops for the sale of European drugs and for the employment in them of dispensers duly certified as fit persons to be entrusted with such duties."

In 1886 Dr. WARDEN thus commented on the above resolution:—

"It is true as was pointed out in the resolution on the Chemical Examiner's report for 1884 that the subject is beset with many difficulties. But there does not appear to be any valid reason why an attempt should not be made to restrict the sale of some, if not all, poisons. The state of society in Bengal is hardly likely to change materially for a few centuries. A complete bill similar to the English Poison Schedule of the Pharmacy Act, it is utopian to anticipate for India. The provision in the Bengal Municipal Act 1884 for registration of shops for the sale of European drugs is apparently intended to check the ignorant compounding of English drugs and medicines by unqualified druggists and for the registration of shops for the sale of European drugs. But this legislation, though highly desirable, is surely less important than some enactment which would prevent *baniyas* and native drug vendors from indiscriminately selling arsenic to any body who can afford to purchase it. The provision of the Bengal Municipal Act protects to some extent the European community and the higher educated classes of the natives. But the lower classes, most in need of protection, are not benefited."

In 1887 Dr. WARDEN again wrote as follows:—

"The increase for the last two years in the number of cases in which arsenic was detected in suspected articles, when taken into consideration with the fact that similar increase is also apparent for the same periods in the number

of cases in which arsenic was detected in human viscera, points to the fact that it is almost unknown to the consciousness of the people, and to the indifference to the indiscriminate sale of poisons. Legally, no enactment would prevent individuals from destroying themselves with poison if so disposed. Legislation is required to prevent the use of poison for homicidal purposes, and the one poison which is used in India for this purpose is arsenic.

The matter has also attracted the attention of the *British Medical Journal*. The following is an extract from an article published in the October number of 1892, dealing with the free sale of poisons in India:—

"We have from time to time called attention to the great danger to the public and the serious encouragement to the criminal tendencies occasioned by the unrestricted traffic in deadly poisons in India. We are aware of the old argument of those who counsel non-interference, viz., that in a country where deadly herbs grow in every road-side and open space, it is impossible to prevent their improper use. But the argument scarcely applies to the wholesale and retail dealings in *white arsenic*, which we understand can be bought without let or hindrance or any record of the sale or purchase, in every village bazar throughout the country. The Chemical Examiners to the various Governments invariably show that in about three-fourths of the cases in which poison is used with criminal intent, the article selected is *white arsenic*, not only for putting away of obnoxious individuals, but for the destruction of the cattle as well."

Such then are some of the recommendations which have been made from time to time during fifty years. What has been the result?

Result of previous recommendations.—The result so far has been the passing of certain sections of the Bengal Municipal Act of 1884 and of the Calcutta Municipal Consolidation Act. For convenience of reference these two sections are given in the foot-note below. They secure, as already stated, that all shops engaged in the retail trade of British Pharmacopoeia drugs should be registered, and that the compounders employed in these registered shops should be properly qualified.

No objection of any kind can reasonably be advanced against an Act directing the registration of shops engaged in the sale of medicines, and the employment therein of properly qualified persons. Measures of this kind are enacted not only in order to obtain the accurate compounding of medicines, but also in order to avoid those mistakes which arise from errors in the identification of drugs.

No doubt the operation of the Act in question has been to greatly minimise the risks arising from ignorant or careless compounding, so far as the majority of the British

Bengal Municipal Act, Section 332.—No shop or place shall be kept for the retail sale of drugs recognised by the British Pharmacopoeia not being also articles of ordinary domestic consumption unless the same shall have been registered in the Office of the Commissioners. Any keeper of such shop or place failing to register the same within two months after the section shall come into force or within two months from the date of the establishment of such place shall be liable to a fine not exceeding one hundred rupees. The Commissioners shall upon registration grant the keeper of such shop or place a license, which he shall be bound to display in some conspicuous part of his premises.

Pharmacopoeia drugs are dispensed. But the majority of people benefited thereby, especially the poor.

For even in the towns a very large proportion of the people, when sick, are treated by means of indigenous medicines.

Inapplicability of exempting indigenous medicines from the operation of the Act.—It would naturally be suggested that the sale of indigenous drugs ought to be attended with a certain amount of care. Why then are indigenous drugs exempted from the operation of the Act?

A poison does not cease to be a poison because it happens to be excluded from the British Pharmacopoeia.

As already stated, the Act applies to British Pharmacopoeia drugs only. There are however certain drugs common both to the British Pharmacopoeia and to the indigenous list, among them being *aconite*, *nux vomica* and certain *arsenical* and *mercurial preparations*.

The drugs common to both lists are specially exempted from the operation of the Act, provided they are not sold in shops where British Pharmacopoeia drugs are dispensed on prescription. One is prompted to ask, whether such drugs as *aconite* and *arsenic* change their character with change of locality, and whether they cease to be dangerous when dispensed without the help of a prescription.

The special exemption of indigenous drugs from the restrictions imposed by the Municipal Act, was no doubt made with the wise object of interfering with the practice of indigenous medicine as little as possible. But the

No person shall compound, mix, prepare, dispense or sell any drug in any such registered shop or place unless he be duly certified as a fit person to be entrusted with such duties under rules made for that purpose by the Local Government.

Provided that the provisions contained in this second clause of the section shall not come into operation until after the expiration of a period of six months from the publication of a notification to that effect in the *Calcutta Gazette* by the Local Government:—

"Nothing contained in this section shall be construed to apply to the sale of drugs, used by practitioners of indigenous medicines, whether recognised by the British Pharmacopoeia or not, when such drugs are not sold in a shop or place where medicines recognised by such Pharmacopoeia are dispensed on prescription."

Calcutta Municipal Consolidation Act, Section 268.—No shop or place be kept for the retail sale of drugs not being also articles of ordinary domestic consumption, unless the same shall have been registered in the office of the Commissioners. Any keeper of such shop or place failing to register the same within two months of the passing of this Act, or within two months from the date of the establishment of such place, shall be liable to a fine not exceeding Rs. 100. The Commissioners shall, upon registration, grant the keeper of such shop or place a license, which he shall be bound to display in some conspicuous part of his premises.

No person shall compound, mix, prepare, dispense or sell any drug in any such registered shop or place unless he be duly certified as a fit person to be entrusted with such duties under rules made for that purpose by the Local Government.

Any person not being a holder of such certificate, who shall compound, mix, prepare or sell any drugs in any such registered shop or place, shall, on conviction before a Magistrate, be liable to a fine not exceeding Rs. 50 for each offence, and any owner, occupier or keeper of any such shop or place who shall employ any such uncertified person to perform any one or more of such duties shall, on conviction before a Magistrate, be liable to a fine not exceeding Rs. 200, and shall be further liable at the discretion of such Magistrate to suspend his license.

Nothing in this section contained shall be construed to apply to the sale of drugs used by practitioners of indigenous medicines when such drugs are not sold in a shop or place where medicines are dispensed on prescription.

practice of indigenous medicine does not consist solely in the use of poisons, and it will not be interfered with if the sale of deadly poisons is entirely removed from the hands of the ignorant *bumiah* and *badias* and entrusted where necessary to the practitioners of indigenous medicine themselves.

The provisions of the Act in its present form are difficult to enforce, as it contains no schedule of European drugs, which may be sold by *bumiahs* on the supposition that they are utilized in the practice of indigenous medicine.

It is reported that as a consequence of this, a large sale of European drugs is carried on in some *bumiah*'s shops.

Unrestricted wholesale trade in European drugs in Calcutta.—In Calcutta there is a very considerable wholesale trade in European and other drugs, in addition to the retail trade of the chemists and *bumiah*'s shops. The wholesale dealers reside chiefly in Burrabazar and Chandney, and carry on their business subject to no restrictions whatever. White arsenic, chloral hydrate, hydrocyanic acid, morphine and strychnine may be purchased at one of these wholesale dealer's shops in large quantity by any individual, however unfitted to be in possession of poisonous drugs.

Wholesale purchase of Medicine for domestic use; its mischief.—It may be said that the wholesale purchase of medicine even for domestic use in cases of sickness is the common practice among the educated inhabitants of the large towns of Bengal, provided no compounding is required. A private person, when directed by his medical adviser to take a certain medicine, or when taking a medicine on his own responsibility, usually purchases a considerable quantity at one time from a retail or wholesale druggist, without of necessity presenting a prescription. In such instances the dose is measured by the individual at his own home and not by the chemist.

Provided the drugs bought and sold in this manner are not in any sense poisonous, no very serious objections can be raised to the plan, which is in addition apparently ratified by the approval of medical practitioners.

But in the case of poisonous drugs, no more dangerous plan could be imagined. At the present time there is no law in India regulating the quantity of a poisonous drug which any single person may be permitted to purchase at one time excepting the case of opium, where the quantity is limited to 2 ounces or enough to poison, may be 20 individuals.

Consequently individuals addicted to the use of morphine, chloral hydrate or any other drug find in India no difficulty in procuring any quantity of the drug for which they have acquired a craving. Needless to say this is only one type of mischief resulting from the present system.

Legitimate functions of wholesale and retail druggists.—If the wholesale druggist was permitted to sell poisons to authorized licensed persons only, and the retail druggist might sell poisons only on prescription, much of the mischief at present being wrought could be prevented.

At the present time the retail druggist may do a wholesale business in poisons or other drugs without let or hindrance, provided he has the purchasers.

Still taking the present condition of the trade in drugs, notwithstanding the enactment of legislative measures, it may now legitimately be urged that these measures require amendment.

(To be continued).

SOME EXPERIMENTS ON TETANUS.

By A. MITRA, BAI BAHADUR, M.B.C.P., L.B.C.A. (Edn.)

Chief Medical Officer, Kashmir.

On the 5th July last, a patient was admitted into the Kashmir State Hospital with fracture of both clavicles, of 7 ribs, of right humerus and the manubrium of the sternum. The patient was a mason, and had fallen from a scaffolding. For two days there was considerable dyspnoea, which however, gradually disappeared, and the patient was apparently progressing towards recovery, when on the 10th day after the injury, lockjaw was noticed. In spite of free exhibition of sedatives and antispasmodics, the case gradually passed from bad to worse, and ended fatally on the 15th day.

This patient was kept in a side room of the military ward of the hospital—a room very well ventilated and lighted and floored with boards with ventilating space below and earth 3 feet from the planks. After the death of the patient the room was fumigated with sulphur and the floor and the bed (a Lawson Tait iron bed) thoroughly washed with carbolic water.

Four days after the death of the patient a robust Pathan cooly, aged 40, was admitted into this room with an injury on the leg caused by a landslip on the Jhelum Valley Road. There was compound comminuted fracture of both bones of the leg and extensive laceration of the soft parts, extending up to the knee-joint. The patient was admitted on the 4th day after injury. Temperature on admission, 99°F., and the wound looked very unhealthy and sloughy. The patient was immediately anesthetized, and amputation of the thigh at the lower third was performed by double flap method. All was progressing well. Temperature did not rise above 101°F. Wound was treated strictly antiseptically by zinc-cyanide of mercury dressing. On the 14th day after the operation, lockjaw was noticed. Soon after, he was in a state of opisthotonus with frequent muscular spasms, and perspired freely. He was able to swallow, and ample nourishment was given. A mixture containing 5 drops of chloroform, 5 of tincture of belladonna, and 10 grains of bromide of potash was given every three hours. The patient was in the habit of smoking *charas*, which was allowed as much as he wanted, as it greatly relieved spasm. On the 19th day the patient died. After death the stump was carefully examined and all nerve-ends were found free, and the ligatures were found to have included nothing but the arteries.

The occurrence of two successive cases of tetanus in one room was striking, and suggested infection by germs. Being thus interested in the question, I conducted some experiments, the results of which I now describe:—

Soon after the death of the patient, a little pus was taken from the wound and mixed with a neutral bullion, 10 c.c. of this was injected into the peritoneal cavity of a fowl. On the 12th day after the injection the serum or blood of this fowl was injected into dogs under following conditions:—

(1). Dog A received an injection of the tetanus poison simultaneously with an injection of the serum.

(2). Dog B received an injection of the serum one hour previous to his being injected with tetanus poison.

(3). Dog C received an injection of the serum one hour after life being injected with the poison.

(4). Dog D received only an injection of the poison.

(5). Dog E received only an injection of serum.

The results were as follow :—

(1). The fowl died on the 12th day, and on *post-mortem* peritonitis was found.

(2). Dog A died on the 7th day with marked muscular spasms.

(3). Dog B died on the 12th day with entirely different symptoms, but with no muscular spasm.

(4). Dog C died on the 4th day with marked muscular spasms.

(5). Dog D died on the 5th day with marked muscular spasm similar to dogs A and C.

(6). Dog E had no symptoms.

Now there were two kinds of death in the above series of experiments: one in which muscular spasms were present and in another they were absent. The fowl died of peritonitis, dogs A, C and D died with spasms, and dog B died not from tetanus, but his death was due to septicæmia, caused by other pathogenic micro-organisms present in my culture which was not an isolated one. The above facts do not prove one way or the other the usefulness of antitoxin serum in the treatment of tetanus; for the artificial tetanus produced in my dogs was not a pure tetanus, because with the poison of tetanus I probably also introduced other pathogenic germs, but they prove :—

(1). That serum of an immunised animal being injected previous to the introduction of the toxine was capable of destroying the tetanic element in it.

(2). If simultaneously injected, the tetanic toxine gets the upper hand.

(3). *A fortiori*, if the toxine gets a start, the serum is incapable of destroying the poison.

(4). That the serum itself is harmless.

From the foregoing facts it appears that tetanus is an infective disease due to a germ. How the germs appeared in the room of our hospital, it is difficult to conjecture, there having been no tetanus in the hospital for nearly five years, nor any in the neighbourhood which I ascertained carefully. There was loose earth under the boarding of the room. Did that afford suitable growing ground for the germ? After the death of the second case similar steps for disinfection, as were taken after the first, were also taken, and on the 8th day after the death of the second patient it was opened for admittance of other cases, though for nearly two months no important surgical case was allowed in it.

If the antitoxin serum is able to withstand the effects of tetanus poison if introduced before infection takes place, and as tetanus is a most dreadful disease which adds to a certain extent to the mortality after severe operations and injury, why should we not take the precaution of injecting the antitoxin serum whenever it may be available in such cases of operations or injury after which tetanus may likely follow?

BILIARY CIRRHOSIS OF CHILDREN.*

BY JOGENDRO NATH GHOSH, L.M.S.

Teacher of Midwifery, Campbell Medical School.

Literature and general features of the disease.—Under this title, I venture to lay before you some facts connected with what I may call a new disease, which has lately appeared among the children of certain classes in Calcutta and other parts of Lower Bengal. On account of its generally unsuccessful treatment and fatal termination, it has, of late, drawn considerable attention and been the subject of serious thought in the minds of medical practitioners and the general public. The literature on the subject of this disease is still very meagre.

The peculiar features of the disease are that its onset is insidious, that it usually prevails among infants under the age of one year, that it seldom attacks children after they have passed the third year. The attack generally commences on the 7th or the 8th month, chiefly at the period of dentition or the mother's next conception. The children of some parents are particularly liable to the disease. In one family, I have observed fourteen children of the same parents die one after the other. Cases of attack on the third or fourth month, or even a few days immediately after birth of the child, have also been noted. Children in Calcutta, as well as in the districts of Bengal, whether malarious or non-malarious, are equally subject to it. It makes no difference between the children of the intemperate, the sober or the teetotaler. It spares neither rich nor poor, though the well-fed children of the wealthy and the middle classes are more liable to it than the ill-fed children of the poorer classes. Mahomedan and Eurasian children suffer less than the Hindus. Hardly any cases are seen among Europeans. In those families where the disease prevailed, I noticed a few children escape apparently from being nourished by healthy wet nurses. When the disease was first noticed in Calcutta, more cases were found among male than among female children; but of late the proportion seems to be less, and more female children than formerly now come under the notice of practitioners. Still, I shall point this out as a peculiar feature of the disease. Another peculiarity noticed is that the female children mostly attacked are usually the first-born of the parents, and who are necessarily the objects of great care in a family.

It has been observed that a female child escapes the malady after the successive deaths of several males that preceded her, though again the next male child succumbs to it. Children of very healthy parents are not exempt, and the disease appears to be quite unconnected with long standing purulent discharges, scrofula, syphilis, malaria, fever, or any chronic constitutional disease. In a family of several brothers living in the same house and under exactly the same conditions as regards food, it is rare to find the children of more than one of the brothers affected with the disease. In one family of three brothers living together under the Hindu family system, one brother had fourteen children, most of whom died about one year old, while the ten children of the other brothers remained quite healthy. This is the rule, but exceptions may have

* A paper read at the Indian Medical Congress and sent to the Secretary for publication.

comes under observation in which the children of two brothers living together were affected by the disease.

The enlargement of the liver is gradual, and is unattended with pain. The subsequent contraction is, however, rapid. The termination is generally fatal, death being mostly due to cholemia. The disease runs its course from 3 to 12 months, though one case has been known to end fatally within a fortnight of the attack, and the patients in two other cases, which came under my observation, lingered on for three years, and in these cases change of climate was tried in vain. In my experience, out of about 400 cases, only 6 recovered, making a mortality of 98.5 per cent. The diagnosis in the case of 3 is, however, open to doubt. Of the remaining 3, one child was sent out for change at the very commencement of the disease, and two recovered after the first symptoms had fully manifested, but in none of these cases was there persistent jaundice, which in my experience is a fatal sign.

Historical Sketch.—In 1877, a few cases came under my observation. All these patients were in the last stage of cholera, with contracted liver, ascites and edema of hands and feet. I mistook some of these cases for malarious enlargement followed by cirrhosis of the liver. During the next two years, I carefully watched a few more cases, I found the liver hard and resistant to the touch, and the enlargement was great, but accompanied with little or no pain, and slight fever. At the last stage, jaundice set in, the liver gradually contracted, and the little patients died from bile poisoning. The disease was then supposed to be some of degenerative liver of children and was called "Amyloid, Fatty or Infantile liver." Since that time I had occasion to notice numerous cases of this kind, and the disease seems to be spreading not only in Calcutta, but also in the districts, as cases are frequently brought to town for treatment. I consulted several leading and eminent physicians, both European and Indian, but none were able to throw much light on the diagnosis and treatment of this serious malady. Since 1887, a number of cases were brought before the meetings of the Calcutta Medical Society, and papers read and the subject fully discussed, but until recently, no definite solution was arrived at regarding the true nature of the disease. Parental objection and caste-prejudice stood in the way of a thorough and extended investigation into the nature of the disease by *post-mortem* examination in well-authenticated cases. The medical science, therefore, is deeply indebted to Surgeon-Major J. B. GIBBONS for the light he has now thrown on the subject, and the medical profession of Bengal for the correction of errors under which it hitherto hopelessly labored. As Professor of Pathology in the Medical College, Calcutta, Dr. Gibbons always took a particular and an active interest in the disease, and he availed himself of the opportunity to hold *post-mortem* examinations in a few hospital cases, which led to the discovery that the disease is a form of BILIARY CIRRHOSIS, presenting features which distinguish it from diseases of a similar nature described in medical books. He placed the results of his investigation and discovery before the Medical Society, exhibiting and illustrating motions of the diseased liver, and thus placing beyond all doubt the true nature of the disease. Since that time the medical profession has termed it "Biliary cirrhosis of children."

Definition.—The disease may be defined now as a painless enlargement of the liver, hard and resistant to the feel, beginning with slight fever, occurring in children only, and terminating almost invariably in death.

SYMPTOMATOLOGY: First symptoms.—The onset of the disease is so very insidious that, as a rule, nothing is noticed by the parents until the liver has attained a considerable size. The early symptoms which attract the mother's notice are nausea, occasional vomiting, sallow complexion, warmth of hands and feet and a certain amount of constipation with straining at stools. The child also refuses food, gets irritable, loses its cheerfulness, wishes to lie down on damp ground and gets a little fever towards night or early in the morning. Some thirst also is noticed, as the child looks wistful at the sight of water and tries to lay hold of the vessel containing it. A slight icteric tinge is also sometimes observed in the eyes (conjunctivæ).

Enlargement.—When the child is brought under a physician's observation, the liver appears enlarged, at times so considerably that it extends as far as the umbilicus or even beyond it to the iliac crest. The anterior margin of the liver is well defined, prominent at first, and feels smooth and rounded; gradually it becomes thinner, assuming the shape of a knife-back-edge, and at the last stage of the disease it can be grasped by the fingers. The enlargement is uniform, the liver being hard and resistant; painless first, but slightly painful when jaundice supervenes. The left lobe generally enlarges first, sometimes reaching as far as the spleen, which also in most cases enlarges simultaneously. Occasionally the right lobe enlarges so much that its anterior border overlaps the left lobe, and the notch between the lobes is so displaced to the left as to be mistaken for the hilum of the spleen. At this stage the liver goes on enlarging, gradually filling up the abdomen, which bulges out, the superficial veins becoming prominent. As the liver enlarges, the child becomes more markedly ill, with fever, loss of appetite, more pronounced jaundice, accumulation of fluid, &c.

General appearance.—The general appearance of the patient presents no marked change in the early stage of the disease. After a short time the features exhibit a dusky appearance; later on the skin becomes harsh and dry, the complexion slightly yellow; the feet and hands may become puffy; this last symptom usually disappears after a few days, but returns again.

Spleen is generally hard and enlarged, but not to a considerable extent.

Constipation is a well-marked, obstinate symptom. The stools are yellowish at first, then clayey and muddy, and lastly whitish and devoid of bile.

Urine at the commencement is clear, but gradually becomes bile-tinged, and lastly deep yellow, unfruct-colored, the stain of which does not disappear on washing. There is very little or no perspiration.

Fever is slight at the beginning, but it increases with the progress of the disease, and the maximum is reached when the jaundice is pronounced. There is no shivering or ague with the fever; in some cases it remains continuous, while in a few it only appears late with the jaundice.

Ascites.—In some cases a certain amount of fluid accumulates in the peritoneal cavity, with edema of hands and feet.

Jaundice.—The most important symptom as regards prognosis is the appearance of jaundice. In the early stage, a slight discoloration of the body may occur, but this is not to be confounded with the deep and persistent jaundice which attends the later stage of the disease. At this time the whole body gets discolored and the conjunctivae become bile-stained. The onset of the intense and persistent jaundice, which occurs in the later stage of the disease, is a symptom of the gravest import.

Contraction of the liver.—After the appearance of the jaundice, the size of the liver begins to undergo diminution. In a few cases, I have observed the contraction so very rapid that in 48 hours it has come up from the umbilicus to the inside of the costal arch. This contraction has often been mistaken for a favourable symptom.

Etiology.—The main cause of this serious malady is, I believe, unwholesome food and faulty digestion. The milk either of the mother or of the cow is the principal article of food for our infants. Mahomedans and Eurasians feed their children occasionally with animal broth. The Hindu mother always nourishes her children from her own breast, and it is among the Hindus that the disease is most prevalent.

First, as regards the mother's milk.—The practice is not uncommon for a mother in a state of pregnancy to suckle her child. Her system must then be undergoing a change, rendering her milk quite unfit for the child in her lap. The double strain to which she is subjected may also contribute to a further deterioration of the nourishment she can afford at this time. Indeed, numerous cases have been noticed of children being attacked with the disease immediately after her next pregnancy, specially in cases when the children of the same parents died one after the other of this malady. In the case of the family of which a history will be given hereafter, and in which 14 children successively died of this disease, I was able to clearly establish this point. The mother usually became pregnant from 8 to 12 months after each delivery, but still continued to suckle the child on the lap. Within a short time, the signs of the disease used to appear in the suckling child. As I have noticed this fact in many other cases, I am inclined to attach very great importance to it as one of the potent causes of the disease. I am also of opinion that the Bengali race, specially the females of the middle and the richer classes, are gradually undergoing degeneration, and getting indolent, dyspeptic and enfeebled by early marriage and premature and frequent pregnancies. All circumstances which tend to lower the mother's health equally tell against the health of the children born of her. A healthy child cannot be expected from an unhealthy mother.

Second, as regards cow's milk.—This, the next best diet of our infants is so much adulterated in large centres of population that it may be pronounced as quite unsuitable for infant food. Besides adulteration of the milk, the cows are kept in unhealthy sheds, and fed on refuse and other unwholesome food-substances. Great carelessness also prevails in the matter of keeping the milk. The vessels are not properly cleaned, and stale milk is often acid as fresh. In feeding the child with cow's milk, even the parents themselves do not take sufficient care as regards

the quality of the substance used. Stale milk is given to the child late at night or early in the morning, and the unsuitability of the milk due to a difference in the age of the calf and that of the child is never taken into consideration.

Irregularity in feeding and over-feeding.—No regularity is observed in feeding the child. Whenever it cries or gets cross, in order to pacify it, a certain amount of milk is poured down its throat, irrespective of quantity or quality, or the time or interval after which it is fed. Male children, who are generally the objects of great solicitude in a Hindu household, are over-fed with pure cow's milk, under the impression that it would make them robust and healthy and, as stated before, the disease is more prevalent among males than among females.

Other causes.—The primary cause of the disease may, therefore, be safely stated as mal-assimilation. Nature is also outraged in other directions. For instance, many children are not fed with any other substance but milk even after the cutting of teeth. Besides these causes, the over-crowding and general unsanitary condition of houses in towns, where the high rents compel people to crowd together, absence of exercise, and want of fresh air must by deteriorating the health of the child render it susceptible to disease.

Predisposition.—There also appears to be a predisposition in many cases. This predisposition seems to be inherited, as is proved by cases in which the children get the disease only a few days after birth; by successive deaths of a number of children in the same family, in spite of all the precautions taken under the best medical advice; and by its occurrence among children of uterine brothers and sisters.

In support of the above arguments, I will now cite only a few of the numerous cases that came under my immediate observation:

(1) A, present age 52, has been the father of 18 children by the same wife, all dead. Of the first 4 the cause of death is uncertain, and the next 8 are supposed to have died of biliary cirrhosis, but I cannot be positive about them. I can, however, certify that the remaining 11 died of biliary cirrhosis.

The father of A lived to a good old age and died of diabetes and asthma; his mother died of fever and liver complaint. He married thrice. By the first wife he had four daughters, all dead, but none from biliary cirrhosis. In order to have a male issue, he married again when the first wife was living. By the second wife he got a son, but both the mother and the child died shortly after, though not from biliary cirrhosis. He married a third time, while the first wife was still living. By the third wife he had two sons and one daughter. After this, the first wife gave birth to A.

A is one of three brothers and a sister, though not uterine. The two brothers are dead: one died of cancer of the throat and the other from gangrene due to diabetes. Both the brothers were married and had children. The eldest had four sons and three daughters, all healthy. The other brother had three sons and four daughters, all healthy; the sister had two sons and two daughters, all healthy. A himself once suffered for some years from

disturbance of digestion and the consequent anorexia, but is now cured, and at present he is in fair health.

A's wife has two brothers and two sisters, all married and with families. The brothers have children; all are living. The sister has only one child, which is living. The other sister had seven children, of whom two died, but not from liver disease.

Briefly, neither among the father's nor the mother's relations have any of the children shown the disease. The wife's father is dead, but her mother is living. The wife enjoyed good health until recently, when she began to suffer from dyspepsia. She was married at the age of 11, and her first child was born when she was 13. She had altogether 18 children; no miscarriage. The children were born at intervals of 15 to 24 months, and lived to the average age of 12 months; only one child reached the age of 2½ years. Neither A nor his wife ever suffered from syphilis, scrofula or rickets. I saw the last 14 children, and am positive that 11 of them died of biliary cirrhosis. Some of these succumbed shortly after the disease appeared; others lingered for a year or more. The average duration of the disease was about 6 months. Death, as a rule, occurred with well-marked signs of cholemia, after the contraction of the enlarged liver had begun.

(2) The history of another family illustrates well some of the peculiar features of the disease. B, a qualified medical man, resident of Calcutta, some years ago left his wife and family in his village home in a malarious district. His wife had altogether 13 conceptions. Numbers 1 and 2 miscarried; 3 and 4 still-born; 5th, a female child, died of fever with enlarged liver and jaundice. This occurred some years ago before the subject of infantile liver attracted attention, and the death was attributed to malaria. Nos. 6 and 7, twins, both males; one died immediately after birth; the other got enlarged liver and jaundice and was removed to Calcutta for treatment, where the family have lived ever since. The disease of the child was now diagnosed as infantile liver; it died on the 15th month. The 8th child, a daughter, was born in Calcutta and was nourished by the mother; she is healthy, now married. The 9th was a son, nourished by the mother, who died of biliary cirrhosis, though the disease was recognised early and every effort made to save him, including change of climate. The 10th child, also a boy, was never given the mother's breast, but was suckled by a healthy relative, who happened to have been delivered at the time and who had sufficient nourishment for both children. This boy is living and quite healthy. About two years after the birth of this boy, the 11th child, another boy, was born. He was suckled by the mother and is also healthy. One daughter (12th) was subsequently born and has lived. The 13th was still-born and the 14th, a daughter, is living and healthy. Not taking into account the miscarriages and the still-born, out of a family of 9 children, 3 died, 2 certainly from biliary cirrhosis, the other probably from the same cause. As to the history of the parents, the father, B, is not a very strong man, though never ill. At one time he had some enlarged glands in the neck which suppurated. But he suffered from no other disease. The mother is a

healthy, robust woman. The father had two brothers; one had three children, of whom one son died of biliary cirrhosis.

(3) The following case is I think of importance:—C has been married three times. By the first wife there was one child, healthy; by the second wife there was one child, also healthy; by the third wife he had three children, all of whom died of biliary cirrhosis. C is healthy, and his third wife is healthy too, though not very robust.

(4) Yet another case of the above kind may be mentioned. D, an Assistant Surgeon, was married thrice. By his first wife he had one son and one daughter; both healthy. His second wife was childless. By his third wife he had six children; first two daughters, all healthy. The third, a son, being the first male, was given from birth undiluted cow's milk in addition to mother's nourishment. The mother was a healthy woman and had plenty of milk. This child died of biliary cirrhosis. The others are healthy.

Let me cite one more instance. (5) E has two wives, both have children. First wife's only child died of biliary cirrhosis. Second wife's children died from other causes. No child alive.

Many instances may be mentioned of the disease having attacked the children of only one wife of the same husband, while those of the others having enjoyed a perfect immunity from it.

Diagnosis.—It is difficult to diagnose the disease in its early stage. But once the first symptoms are developed, the generally uniform, painless enlargement of the liver, which is firm and resistant, leaves no doubt as to the nature of the disease. The enlargement becomes enormous, and subsequently contraction ensues with the usual symptoms mentioned before. It may be stated here that the little patient can be best examined when it is asleep.

Differentiation.—The disease may be mistaken for amyloid liver, but the latter is very rare in this country, and its causes, as a rule, are absent. The characteristic enlargement and the progress of the disease, however, soon clear away all doubt. From enlargement of the liver connected with malaria it may be distinguished by its occurrence among children removed from ordinary malarious conditions. It is especially the disease of large towns like Calcutta, and is easily distinguished from the absence of features which form the principal characteristics of malarious fever. The points which differentiate Biliary Cirrhosis from other liver diseases of a similar nature are given by me in detail in the comparative tables published in the report of the proceedings of the Calcutta Medical Society for December 1890.

Duration.—As said before, the attack generally takes place when the child is less than a year old. The duration of the disease is from three to six months, death generally occurring from the 15th to the 18th month of life. In exceptional cases which came under my observation, death on the one hand occurred within a couple of weeks, while on the other, the patient lingered on for three years.

Prognosis.—The prognosis is extremely unfavorable and gloomy. In my experience, out of about 400 cases, only six recovered, but in three of these the diagnosis is open to doubt.

Morbid Anatomy and Pathology.—For an account of the morbid anatomy and pathology of the disease, I would refer you to the article written by Dr. J. B. Giasone in the *Scientific Memoirs*, Part VI, and to the papers which lie read before the Calcutta Medical Society.

Treatment: Instructions not carried out.—Hitherto the results of treatment have been very unfavorable, even with cases which have been under observation from the early stage. I believe these unfortunate results are mainly to be ascribed to the difficulty which exists in having any line of treatment carried out in its entirety. I refer especially to the difficulty in the matter of food. I place the most reliance in a complete change of diet, holding that the disease is mainly due to unwholesome food. Much difficulty is experienced in getting the parents to carry out the instructions in this matter. When a case occurs in a suckling-child, the first instruction given is that the mother should at once stop giving her breast to the child, and to feed it with some other food. This is seldom carried out. The reasons for this are obvious; the child accustomed to suckle naturally shews a reluctance to take to any other food, and the mother hearing its cries, gives way and suckles it, notwithstanding all instructions to the contrary. This is especially the case at night, when the child lies alongside its mother.

Change of diet.—As said before, the treatment which I now adopt and which appears to offer the best hope of success, is mainly dietetic. When I see a case, I enquire as to the food given to the child and generally make a complete change in this. I always forbid the mother's nourishment and substitute in the case of young infants a healthy wet-nurse if available, or, if not, a specified quantity of pure cow's milk diluted with water in proportion to the age of the child, and sweetened with sugar.

When I first saw cases of this disease, I tried different kinds of food. In some cases, I stopped milk of every description altogether, and fed the children on soup and various kinds of artificial food,—MELLIN'S, NESTLÉ'S, BÉNGAL'S, &c. This was the diet I adopted in the case of young infants. To older children, who had out some teeth, I gave solid food in small quantities, such as,—biscuits, bread, home-made *rotis*, a little rice and other grains, together with *dal*, fish-soup and milk or only the latter. In several cases, I fed the children entirely on asses' milk. Briefly, I may say that I believe I tried every kind of food. But as I have remarked, the directions about diet were seldom carried out by the parents for more than a few days, so that the want of success is not to be attributed to the line of treatment adopted in the matter of food, but rather to the failure in carrying out the instructions. In the case of older, post-suckling children, difficulty also exists in getting the parents to prepare the food ordered and to prevent the child getting substances of an unsuitable character. In most cases, however, I find my instructions fairly carried out for a week or so, but the parents observing no immediate marked improvement, begin to doubt in the efficacy of dietary measures, and revert to the food the child was in the habit of taking before the attack of the disease. In the matter of administration of medicines, much less trouble is experienced, the medicines being usually given according to the directions.

Therapeutically, medicines have been tried with the view of combating the morbid process going on in the liver, and for this purpose mercury, iodide of potash, hydrochlorate of ammonia, phosphate of soda, &c., have been used in all forms, but I cannot attribute any benefit to them.

To combat the obstinate constipation, which is a marked feature of the disease, laxatives and cholagogue purgatives have been used. My experience, is that in the early stage, no great difficulty is met with in keeping the bowels open, and any simple purgative acts very well at this time. But as the disease advances, it will be found that the purgatives used lose their effect and have to be given in increasingly large doses. This constipation is one of the difficulties which the physician has to overcome. Of late, I have been using the freshly prepared juice of the leaves of *nyctanthes arborescens* or the *will* flower tree, in teaspoonful doses taken in the early morning, and this has usually acted well, though when the stage of marked jaundice is reached, it, like every other drug, appears to be powerless.

External applications over the liver, such as blisters, mercurial ointments, and iodine have been tried, as also nitro-muriatic acid packs, &c. None of these seem to have any influence on the progress of the disease, though at times no doubt, they may be useful.

Change of climate is undoubtedly beneficial in the early stage, but later has no effect. Its influence is probably due to the improvement in general health.

On the whole, I have found that when the disease has reached the stage of persistent jaundice and contraction of the enlarged liver, little benefit can be hoped for. It is in the early stage that the change of food and improvement in general hygiene can be expected to lead to recovery.

Conclusion.—I have endeavoured to lay before you the nature of a new disease which is daily bringing death and desolation to numerous households in Bengal. The mother's tears and the father's sobs must often have rent the heart of many a practitioner in Calcutta. If the parents' sorrow is intense, the physician's shame is not the less deep. He daily sees before his eyes an innocent little infant, striving to be playful in spite of the cruel disease, but slowly and surely dwindling away to death. Yet, he can do nothing to save the little thing from an untimely end. In my opinion, the disease ought not to be fatal, at least its pathology does not justify such a hopeless prognosis. I therefore earnestly appeal to you to pay attention to this matter, to try to discover some effectual remedy, and to save the profession from the helplessness under which it now labors.

PILOCARPINE IN RHEUMATISM.

DR. DRAPIER, of Auvillers-les-Forges, calls attention to the fact that, though sodium salicylate may be regarded as a specific in articular rheumatism, it sometimes causes toxic symptoms so grave as to render its use impossible. In one such case, a patient who suffered from two or three attacks of rheumatism yearly, he used hypodermatic injections of pilocarpine, formerly advocated for the disease, using 0.01 gramme (1 grain), which led to complete recovery within ten days.—*Universel Med. Jour.*

THE ANTIPYRETIC TREATMENT OF FEVERS.

By BRIG. CAPT. GEO. S. THOMSON, M.B., C.M., I. M. S.,
Dacca.

In this paper two questions have been proposed for answer: (1) What is the best modern treatment of fevers? (2) Should antipyretics be used in the routine treatment of fevers? These questions may be best solved by contrasting the methods of treatment in vogue some seven years ago, with the practice that increased clinical and personal experience have convinced me as being most satisfactory and efficient. On my arrival in this country in 1888, diaphoretic mixture and quinine formed the routine treatment for an ordinary case of ague. At that time I had with me 2 ozs. of antifebrin, and began to use it for obstinate cases of ague of both remittent and intermittent type. Patients getting diaphoretic and quinine mixture used to remain 20 to 30 days in hospital, whereas those who were on antifebrin and antiperiodics went out in 4 to 5 days.

Cases, side by side, as far as possible under the same hygienic conditions, and presenting as nearly as can be, the same severity and type of disease, and similar constitutions, were treated in three groups for the purpose of instituting a comparison. Some were treated with Aq. camph. and quinine; some with mist. diaphoretic and quinine; and some with antifebrin and antipyrin alone; and with these drugs combined with quinine alternately. In a short time one was convinced of the superiority of the use of antipyretics.

(1). By the rapidity of recovery; (2) by the safety in use; (3) by the satisfaction in the feelings of the patient.

The dose usually administered was 5 grains every time the temperature rose to 102°F. or over; and at the time of return, or expected return of the paroxysm.

* The patients used to ask for the "powder" medicine (antifebrin), and always felt their worst symptoms relieved as if by magic; the headache, pain in the loins, back and limbs disappeared in from half to two hours' time; the patient fell into a sleep, or perspired, and woke up with a sense of great relief and ready to take nourishment and quinine with some fair chance of its absorption and assimilation. A further and more extended trial of antifebrin and antipyrin in all forms of ague and fevers has led to the adoption of a combination of both drugs in suitable dosage, i.e., 5 grains of each, administered dry in powder, with a mouthful of water to assist in swallowing; as a safe, satisfactory, and effectual treatment. Phenacetin has also been used but, it has not proved so satisfactory as the combination of the other antipyretics, for with the painful nervous symptoms and (in some patients) with head symptoms, it seemed to quiet the patient without controlling the fever. The use of the combination of the two drugs is based on their physiological action, as antifebrin begins to act on the high temperature a short time (half an hour) after administration, and reaches its maximum effect quickly, i.e., at the end of two hours; whereas antipyrin acts more slowly, taking effect two hours after being ingested, and has a more prolonged action, up to 8 hours afterwards. The antifebrin knocks down the temperature rapidly and keeps it down till the antipyrin

comes late action slowly and persistently comparatively, and thus the patient has some hours of freedom from excessive temperature, and relief from harrying and wearying head symptoms. In my own person I have frequently cut short an attack of ague by a dose of the combined antipyretics. In one instance the bed shook violently under me from repeated and great shiverings, the head was hot, dull, and heavy, the eyeballs painful; light and noise acutely unbearable, and prostration complete; yet in two hours' time I felt perfectly well and able to sit up, move about, and take food with all symptoms of the attack completely removed! In the doses noted the ill-effects met with by others have never occurred in my experience; and during 7 years' use of this formula among upwards of 50 sick daily, and in a population of about 10,000 people, no drawback to the usefulness of the drugs has been noticed by assistants, Hospital Assistants, or by me personally.

Besides, it is claimed that in remittent and intermittent fever, hectic fever, pneumonic fever, and the fever of phthisis, antipyretics have not merely a symptomatic, but a really curative action, and with other suitable adjuncts to rational treatment, have resulted in the cure of many cases of such fevers in my hands.

The reckless use of these newer antipyretics in injudiciously high doses, at too short intervals, and too long continued, has engendered an impression that they are dangerous; has limited the general usefulness of the drugs as therapeutic agents; and has brought them into undeserved neglect. Our elder brethren especially, look on them with distrust as a mere pursuit of the latest fadist in medication; but I can assure them that without their aid one feels helpless at the bed-side of a fever-patient and that it is to be borne in mind that their ascribed dangers have been the result of mal-administration of the drugs in most instances or of the use of impure specimens in others.

Without those antipyretics our elder practitioners rely on large doses of quinine, which in the irritated and catarrhal state of the gastro-intestinal mucous membrane, acts as an irritant and cannot be absorbed, or if absorbed at all, causes congestion of the brain and its membranes, and of the liver, and internal organs; and this is especially to be avoided, as those organs are already pathologically congested by the fever, for the cure of which the drug is being given. During the intermission or remission produced by previous antipyretic treatment, or as a natural break in the course of the disease, large or small doses of antiperiodics, such as quinine (5 to 20 grains) with liquor arsenicalis, etc., come in useful, and have a fair chance of being absorbed owing to the quieting of the circulation, and the sedative action of the antipyretics on the nervous symptoms, and consequent reduction of the gastro-intestinal catarrh.

A retrospect of the past seven years' professional work in the treatment of fevers impresses upon my mind the firm conviction that the use of antipyretics in the routine treatment of such diseases is a distinct therapeutic advance. The adoption of such an advantage yields the best hope of successful cases when used with due regard to the accompanying state of the patient under treatment; for the

patient and his disease must be treated as a whole, if misadministration of drugs and mere quackery are to be avoided. It is for the purpose of emphasizing the use of antipyretics as a routine part of the modern treatment of Indian fevers, that I bring forward the claims of antifebrin and antipyrin in this paper. The medical practitioners of a decade ago recommended a purge, diaphoretic, and quinine; and this sums up their medical treatment of a case of ague. Dr. MACLEAN in his article in Quain's dictionary of medicine, (to put it shortly) lays this down as the best classical treatment in malarial fevers, and it is time to insist on the judicious use of antipyretics as a step in advance, for although the majority of medical men use them, the fact has not been prominently brought before the profession for discussion and quasi-official sanction.

If this short paper should have contributed in any way to the solution of the questions at its commencement, it will not have been written in vain.

A MIRROR OF PRACTICE.

A CASE OF HYDATID MOLE.

By SURGEON-CAPTAIN PATRICK HEHIR, M.D., F.R.S.E.,
F.R.C.S.E., D.P.H. (Cantab.)

Lecturer on Pathology and Medicine, His Highness the Nizam's Medical School, Hyderabad.

THE following interesting and typical case of hydatid mole was first seen by me on the 25th October 1893.

Mrs. L., *et. 21 years*, married 11 months, pregnant five months, a tall spare Eurasian girl, stated that four days previously after alighting from a high dog cart at 6 o'clock in the evening, she felt a peculiar stitch-like pain in the epigastrium, and that about 9 o'clock the same evening she noticed a red discharge from the vagina, the pain soon abated, but the discharge increased. Next day the flow was excessive and she had to change every hour. At 4 P.M. violent intermittent fever commenced, which the mother said were exactly like labor pains, and at 9 o'clock that evening she was delivered of a large mass of *hydatid mole* about the size of a cricket ball, but somewhat elongated, the whole looking exactly like a bunch of grapes. She was considerably relieved, but the discharge continued, and after about 12 hours' intermission the pains recommenced and there was profuse hemorrhage, to stop which I was sent for urgently. Arriving at 8-30 A.M. on the 27th, I found that the patient's temperature was 102° F., and every now and then she suffered from slight shivering. It was evident that a piece of the mole remained attached to the placenta, whilst that a certain amount of sepsis poisoning had taken place. On examination the vagina was found intensely hot and dry, and an offensive thick greenish-red liquid was oozing from the mouth of the womb; the os scarcely admitted the tip of the index finger. It was determined to dilate the os at once, which was done with two sponge tents inserted under chloroform at 9 A.M. and 1 P.M. respectively. At 4 P.M. the second tent was removed, and as the patient had taken several doses of hydrate of chloral, the os was now soft and dilatable and soon admitted the largest-sized Hegar's dilator.

Chloroform was again administered, and the os being dilated as much as possible, admitted three fingers, with which the interior of the uterus was cleared of its contents. Finally, it was scraped out with a curette and washed with a 1 in 2,000 peroxide of mercury lotion. The patient's temperature went down to normal by 11 P.M., she slept well that night, all bleeding ceased, and the next day the normal lochia re-appeared, and the patient made an excellent recovery, becoming once more pregnant. I learn, four months subsequently.

This *hydatid mole* formed a most elegant preparation, and is now in the museum of the Hyderabad Medical School.

The case was reported, and the preparation exhibited at one of the meetings of the Secunderabad branch of the British Medical Association, where it was much admired as a typical specimen of this kind of abnormal gestation. Indeed taken together with the clinical history of the case, it is perhaps unique.

The question of the origin of *hydatid moles* has formed the subject of a great deal of controversy, and it cannot be stated that we are even as yet thoroughly acquainted with its pathological relations. Most authorities admit that it has some connection with a defectively-developed or blighted ovum. Accepting this as the origin of the moles generally, we know that there are three forms in which the blighted ovum may appear.

The *first* is that in which the decidua have undergone enormous thickening, forming a thick carneous or fleshy lump, the ovum being altogether insignificant, in consequence of its meagre development, forming the so-called *fleshy mole*:—the *second*, the so-called *apoplexy of the ovum*, in which extravasation occurs between the layers of the decidua and into the placental cells; whilst the *third*, the *hydatidiform mole*, the one under consideration, is said to arise from a disease of the chorionic villi, which develop into large vesicular structures, forming the grape-like bodies attached to the rest of the imperfectly-developed placenta.

These may occur from the death of the embryo early in fetal life, or they may themselves give rise to that occurrence. When the former is the case, the diseased state of the placenta may give rise to a rapid development of the contents of the uterus, so that the *tumor uteri* exceeds in dimensions that of the corresponding period of gestation. The *hydatid mole* was at one time considered to be an enormous dilatation of the cells of the chorionic villi, but this view was dispelled by Dr. GRANT HENRY, and it is now generally admitted that the villi themselves enlarge. Each cell contains a quantity of simple serous fluid.

The patient, after recovering, was in great dread that it would return after each conception, but we can find no evidence to show that such is likely to be the case.

The fact that few practitioners see a case, and that it is seldom that even accoucheurs see more than one in a life time, is sufficient to indicate its rarity and the interest attaching to the histories of recorded cases.

Case.—The above case was written about six months ago, and yesterday I received a note requesting me to give a brief account of the history of the patient's last parturition, as the patient was again under treatment for another malady. Further, two months ago, I learnt by accident

that the husband was being treated for tertiary syphilis, and that he had suffered from secondary syphilis before he was married, a similar relation has been observed in cases of hydatid mole recorded at different times. It may be remarked that at the time of the treatment of my patient, neither husband nor wife presented any signs of specific disease, and inquiries specially directed to ascertain any connection of this kind proved negative. We have here another instance in which the statements of patients and relatives should always be weighed before final acceptance, and in cases involving the utterance of a prognosis.

—:—

SUPPURATING OVARIAN CYST: INCISION: DRAINAGE: RECOVERY.

BY SURGEON-LIEUTENANT C. C. S. BARRY, I. M. S.
Charitable Dispensary, Dinapore.

ON 1st May 1894, I was asked by the Hospital Assistant of the Civil Dispensary, Dinapore, of which I was then in charge, to see his daughter, aged about 30, who he said was very ill and her abdomen much distended. I found the patient, who was living with the Hospital Assistant in his house in the dispensary compound, exceedingly ill. She was lying on her back with both knees drawn up and her face was sunken and had an anxious appearance. The temperature was 104.2; the breathing quick and shallow, and the pulse rapid and feeble; the tongue was dry and dirty, and the bowels constipated. The abdomen was distended. On examination a tumour could, with some difficulty owing to the rigidity of the abdominal walls, be made out extending upwards from the pelvis to about an inch above the umbilicus. The tumour was apparently circumscribed and limited to the central portion of the abdomen, both flanks were resonant; the tumour itself being quite dull and apparently and immediately beneath the abdominal wall. Leave for a vaginal examination could not be obtained. The previous history, which was very uncertain, was that for some months the patient's abdomen had been noticed to be gradually getting larger. There had been no pain till about five days ago, when acute pain came on and had continued since with high fever. The patient had menstruated regularly. She had had two children. Having come to the conclusion the patient was suffering from a suppurating ovarian cyst, I with difficulty got leave to operate, but the patient refused to be moved from the house she was in, which was very dark and unsuited for operating in.

About two hours later, assisted by Surgeon-Captain McGLoughlin, A. M. S., I proceeded to operate. An incision about 4½ inches long was made through the abdominal walls, and the cyst was exposed, lying immediately below the walls of the abdomen. The cyst was quite free in front, but behind was closely adherent to the intestines; it could be traced downward into the pelvis towards the left ovary. As no trocar was available, sponges were packed inside the abdomen round the edges of the incision, and an opening was made in the cyst-wall, and some of its contents evacuated. A thick fluid containing pus and broken down blood clot smelling very fœtid, escaped. When a considerable quantity had thus been got rid of, the opening in the cyst was securely closed with Spencer-Wells clips, and the sponges having been removed, an attempt was

made to separate the cyst from its attachments to the intestine, however, very free oozing of blood was occasioned, and on this account, and owing to the fact that the patient was now very collapsed and the room so dark, that one could not make out the bleeding points, the attempt was given up. The abdomen was therefore well washed out with hot water and the cyst-wall sown to the lower two inches of the abdominal incision, and the rest of the abdominal incision sown up. The opening in the cyst was now enlarged, the contents freely evacuated, and the cyst-cavity washed out with hot water. A large drainage tube was inserted, and a dressing of lint soaked in carbolic acid with a pad of tow applied. No drainage tube was placed in the abdominal cavity; for (though the oozing of blood had been free) it was feared lest this tube might become infected from that draining the cyst-cavity.

At the conclusion of the operation the patient was much collapsed, but after the application of hot flannels to her head and body, she gradually got better. In the evening, about 6 hours after the operation, the temperature was 101°. There had been much discharge from the drainage tube, and the patient appeared decidedly better. The next morning the temperature was normal, profuse diarrhoea had taken place during the night, the bowels acting about nine times, and the patient, though very weak, was improved in condition. After this she continued to improve rapidly, and the temperature, though occasionally rising slightly, (to 99°) remained about normal. She rapidly gained strength, and the discharge, though foul-smelling for the first week, became sweet; it was however considerable in quantity. On 20th May, after having been absent from the station for four days, I found the hospital assistant had, in my absence, allowed the tube to come out, and had been unable to replace it. In consequence, a considerable quantity of pus had collected, and being unable to escape, had set up some constitutional disturbance, the patient's temperature being 104°, and there was considerable pain. Chloroform was again given, and the tube re-inserted and sown to the abdominal wall; the temperature immediately fell, and after this she made a complete though protracted recovery. The tube remained in till the discharge gradually ceased, which it did about five months after the operation, when the wound healed up firmly. The cavity of the cyst was syringed out daily with iodine solution, which was gradually increased in strength. I have not seen the patient since October last, but from a report I have received lately, ten months after the operation, I hear the woman is in excellent health, and gets about and does her household duties as well as she did before she first became ill. The wound remains firmly healed, and no tumour can be felt through the abdominal walls. During convalescence she suffered from much pain in the abdomen from time to time, necessitating the administration of opium; possibly the pain was due to the cyst-wall, as it contracted, dragging on the adhesions to the intestines; the bowels however, acted daily. She now menstruates regularly. I conclude that the violence of the inflammatory action which took place inside the cyst-cavity, assisted possibly by the strong iodine solution with which the cavity was afterwards daily syringed out, may have destroyed the secreting lining-membrane of the cyst and so enabled it to gradually shrink up.

TREATMENT OF COMPOUND FRACTURES BY CREOLIN IRRIGATIONS.

By A. MITRA, L.R.C.P., L.R.C.S. (Edin.)

Chief Medical Officer, Kashmir.

In 1891 I brought to the notice of the profession the successful results obtained by me in the treatment of compound fractures by creolin irrigations by publishing a few cases in the *Indian Medical Gazette*. From 1890 up to the middle of this year I have treated 53 cases of compound fractures of bones of the extremities, in 7 of which circumstances called for amputation, and 46 were treated by irrigation. The result in all of these cases, except two, was very satisfactory. In one only, subsequent amputation was necessary. In two cases there was necrosis, and both of them, after the removal of the sequestra, made excellent recovery. The cases were thus treated:—

If there was any protrusion of fragments, reduction was carefully done, enlarging the wound, if necessary, at the point of greatest resistance. Any portion, which offered hindrance to reduction, was sawn off. The wound was then thoroughly cleansed and washed with 1 in 20 carbolic lotion by means of a gum-elastic catheter fitted to an irrigator. A strip of oiled silk protective, soaked in carbolic lotion, was placed over the wound. The limb was placed in a suitable fixing apparatus and bandaged, leaving bare about 2 inches above and below the wound. The ends of the bones were brought in apposition as much as possible, but no actual union was made by sutures. A mackintosh sheet was slipped below the limb. Several layers of gauze wrung out of carbolic lotion were placed on the wound. A Lister's irrigator filled with strong creolin lotion (1 in 100) was then so arranged as to dribble continuously from a height of about 8 inches. I have tried carbolic acid and also izar, but with creolin the result was better. In cases of compound fractures, where soft parts are completely torn, or when there is extensive laceration, or where main vessels and nerves are severed, or when deep hemorrhage is profuse, or when there are other unfavorable conditions clearly indicating that the fate of the limb is sealed, there is certainly no option left but to amputate, but in cases in which circumstances do not call for immediate amputation, I recommend creolin irrigation as a very effective measure. The result of this treatment has been to me so very encouraging that I make bold to say that the rules for operative measures in compound fractures have now to be recast.

—:O:—

CASES OF SUSPECTED POISONING IN CALCUTTA.

By CHUNI LAL BOSE, M.B., F.C.S.,

Chemical Examiner to the Government of Bengal.

CASE I.—Saroda Debi, Hindu female, of 8, Karbala Tank Lane.

History as furnished by the Police.—The woman was subject to fits. Her husband was an opium-eater and used to keep the drug in one of the pockets of his coat. The deceased was alleged to have stolen the opium and taken it. The husband gave her sulphate of copper as an emetic, but it did not produce vomiting. She suddenly became unconscious and died.

Chemical analysis.—Traces of sulphate of copper detected in the viscera; no other poison detected.

Opinion of the Police Surgeon (who made the post-mortem examination) as to the cause of death.—Death from natural causes.

Verdict of the Jury.—Death from natural causes.

CASE II.—Baddhanath Rakhit, Hindu male of 47, Durj-parah Street.

History as furnished by the Police.—The deceased was a moody. He was picking carlamoms among which he found a white lump which he mistook for chalk, and swallowed it. Vomiting and purging followed. He was removed to the Medical College Hospital, where his stomach was washed out. After 4 days he was discharged apparently cured, but died at home shortly after. His body was taken to the burning ghāt for cremation, which was disallowed by the police, and removed to the morgue for post-mortem examination.

Chemical analysis.—Arsenic detected in the viscera and the washings of the stomach.

Opinion of the Police Surgeon.—Death from arsenical poisoning.

Verdict of the Jury.—Arsenical poisoning self-administered.

CASE III.—W. G. Wagner, Eurasian male, of 6, Carey's Church Lane.

History as furnished by the Police and brought out in evidence.—The man was a plumber. He married a convert woman who was detected carrying on intrigues with an East Indian named Joe Cray and reprimanded by the husband. One day Cray brought some sweatmeat to the house which Mrs. Wagner gave her husband to eat, and which made him sick. A medical man was sent for, who treated the case as one of cholera, but finding that the patient was being neglected, recommended his removal to the Medical College Hospital, where he died within three hours. Death was certified to have resulted from cholera, and the deceased was duly buried. Subsequently the police, on certain information, had the body exhumed and examined. Mrs. Wagner stated also that she had given her husband a pill from a kabiraj to "cool his temper."

Opinion of the Police Surgeon.—Irritant and corrosive poisoning.

Chemical analysis.—Arsenic detected in the portions of the viscera.

Four doses of a mixture said to have been given to the patient, and a number of articles found in the house of the kabiraj were sent for chemical analysis.

The mixture contained extremely minute traces of arsenic. The dose prescribed was $\frac{1}{2}$ m. of liq. arsenicalis; consequently there was only one drop of liq. arsenicalis in the four doses of the mixture sent for examination.

No poison was detected in the stock of medicines found in the house of the kabiraj.

Verdict of the Jury.—Death from arsenical poisoning. Poison was procured by Joe Cray and administered to the deceased by his wife.

Both the accused are being tried by the Police Magistrate.

CASE IV.—Shib Chunder Chakrabarty, Hindu male, of 10 Ramkanta Bose's Lane.

History furnished by the Police.—The man was a priest and addicted to drinking. On the 3rd February at 8 P.M. he went out, and on the 4th, returned home at 9 A.M. quite drunk. He went out again at 11 A.M., but came back at 3 P.M. worse than before. He lay down, but shortly after was found groaning and unconscious. A medical man was called, but the man died the same night.

Chemical analysis.—Neither alcohol nor any other poison detected in the viscera.

*Yours Sincerely,
W. A. Rice.*

Opinion of the Police Surgeon.—Death from alcoholic poisoning.

Verdict of the Jury.—Death from alcoholic poisoning.

CASE V.—Bansari Kumari Das, Hindu female, of 5/1, Raja Rasthrib's Street.

History as furnished by the Police.—Had been suffering from chronic diarrhoea for 6 months previous to her death, and was in the habit of taking small quantities of opium. Her bowels getting more loose, she took a larger quantity on the day of her death. She was removed to the Mayo Hospital, where she died.

Opinion of the Police Surgeon.—Death from opium poisoning. As several pieces of opium were found in the stomach, the viscera were not forwarded for chemical examination.

Verdict of the Jury.—Suicide by opium poisoning.

CASE VI.—Khero Das, Hindu female, of 29, Gopi Kristo Pal's Lane.

History as furnished by the Police.—Her only child was suffering long from a complicated disease, and the case was pronounced hopeless by the medical attendant. She was last seen warming some milk for her child at 5-30 P.M. At 8-30 P.M. she was found unconscious and died between 10 and 11 P.M. the same night. She was apparently in good health a few hours before her death.

Chemical analysis.—Opium detected in the viscera.

Opinion of the Police Surgeon.—Death by opium poisoning.

Verdict of the Jury.—Death by opium poisoning, but how administered, and by whom, not known.

CASE VII.—Netyl Lal Chatterjee, Hindu male, of 37, Kristo Singhee's Lane.

History as furnished by the Police.—The man was a clerk in Messrs. Hoare Miller and Co's. Office. On the 19th February, he returned from office at 5 P.M. and was seen by his son to swallow something from a measure glass; on being asked what it was, the deceased said it was *bhang*. At 11 P.M. he was found drowsy and groaning, and when asked, said that he had taken an excessive quantity of *bhang*. At 9 A.M. the following morning he was found quite unconscious. Medical aid was procured; strychnia was injected under the skin; the stomach washed-out and artificial respiration kept up for nearly two hours; the patient did not rally.

Chemical analysis.—Opium and minute traces of strychnia detected in the viscera and in the washings of the stomach.

Opinion of the Police Surgeon.—Death by opium poisoning.

Verdict of the Jury.—Suicide by opium.

AN EARLY OVARIOTOMIST.

COMMENTING on the labors of DR. ALEXANDER DUNLAP of Springfield, O., who died in January last year at the age of 79, his collaborator, DR. J. C. BEVY, says that DR. DUNLAP was one of those strange characters, who not troubling himself to ascertain the actions of his predecessors or contemporaries and caring less for the approbation or reprobation by others less courageous than himself, studied more in the school of nature and practice than from books, and was continually striking out new paths for himself. Though his method of operation was primitive in the extreme, he performed his first ovariectomy in 1868, when the majority of the profession were bitterly opposed to ostatic operations, and while the *Medical-Chirurgical Review* of London, the then leading journal of the world, said of his operation, "We entirely disbelieve that it has ever been performed with success, nor do we think it ever will." DR. ROBERT LEE, the then leading obstetrician, openly stated that he was watching for a fatal case that he might cause the operator to be legally prosecuted. DR. DUNLAP continued his operations regardless of what the world had to say concerning him, and during his career of over fifty years performed 428 abdominal sections with eighty-three per cent. of recoveries.

OUR PICTURE GALLERY.

SURGEON MAJOR-GENERAL W. R. RICE,
M.D., Q.U.I., M.R.C.S., Eng., C.A.I.
Surgeon-General and Sanitary Commissioner with the Government of India.

THE subject of "Our Picture Gallery" sketch, WILLIAM ROGER RICE, was a distinguished scholar in the Faculty of Medicine in Queen's University, Ireland, and obtained the graduation gold medal and two exhibitions valued at £40. After graduating M.D., and obtaining the diploma of M.R.C.S., England, he entered the Medical Service of the Honorable East India Company, on the 20th November 1856, and was placed on the Bengal Establishment.

After the usual preliminary training at the Calcutta Medical Institutions, at that time authorised, he was appointed to the Bengal European Artillery at Cawnpore in March 1857.

In April of the same year DR. RICE was nominated to be a Civil Surgeon in Oudh, but did not join, for in May 1857 he was appointed Residency Surgeon of Indore.

On the 1st July of that year took part in the defence of the Residency at Indore under SIR HENRY M. DURAND when it was attacked by HOLKAR'S mutinous troops.

In September 1857, DR. RICE was placed in sole medical charge of the Nagpore Field Force, including a battery of European Artillery stationed in the Sitabuldees Fort and in February 1858 he accompanied a siege train en route to join Major-General Sir G. C. WHITLOCK'S Saugor Field Division.

In March 1858 DR. RICE was appointed to the medical charge of the 3rd Bengal Irregular Cavalry, the remains of the 42nd and 52nd Bengal regiments of Native Infantry, the greater part of which regiments had previously mutinied, and also to the charge of the Civil District and new police levies (Nai-chi) 3,000 strong, of Saugor, at that time a district of the Saugor and Nerbudda territories under the Government of the North-Western Provinces.

In 1858 he held medical charge in addition, of a wing of the 50th Madras Native Infantry, of the base hospital of the 3rd Madras European Infantry, and later on, of the 31st Bengal Native Infantry, a full regiment.

In 1859 further duties were added and he was appointed to the charge of General WHITLOCK'S Field Medical Store Depot.

DR. RICE was Staff Surgeon of the Saugor District from July 1858 to January 1860, and in July 1859 he was appointed in addition Medical Storekeeper of the Saugor (provincial) Medical Depot.

In 1860 DR. RICE was appointed substantively, Civil Assistant Surgeon of Saugor, and in 1863 Medical Storekeeper in addition.

In 1865 he was transferred to the civil medical charge of Jubbulpore, a first class station in the Central Provinces and in 1868 he was promoted to the rank of Surgeon-Major, and in 1885 to that of Brigade-Surgeon.

In 1880 and again in 1887 DR. RICE was selected to officiate as Inspector-General of Civil Hospitals, North-Western Provinces and Oudh, and in October of the latter year he was confirmed in that appointment.

In December 1887 he was promoted to the rank of Deputy Surgeon-General, and in 1890 he was appointed to the high office of Surgeon-General and Sanitary Commissioner with the Government of India, from which post he retired on the 29th March 1895, having completed a service of 38 years, 4 months and 9 days, 30 years of which have been spent in the plains of India.

During the above service he spent 15 months on furlough on medical certificate, in 1878-79.

DR. RICE received a Medal for the Indian Mutiny 1857-58, and in 1891 a Good Service Pension was awarded him; in 1872 he was granted an extension of service of 2 years 2 months and 28 days, and he was rewarded with the distinction of a Companionship of the Star of India.

Surgeon Major-General RICE will long be remembered as a true friend of the local profession, who will heartily join in wishing him many years of happiness and prosperity in his retirement.

THE INDIAN MEDICAL RECORD.

1st April, 1895.

PERSONAL HYGIENE AND THE COMMUNION CUP.

It is not, of course, to be expected that a hallowed practice of a Christian church will be easily relinquished, and it speaks well in favor of the growing faith, even of lay people, in preventive medicine, that the warnings of the medical press during the last few years against the dangers of the communion-cup of the Protestant church have resulted in some safe innovations in the system of the administration of the cup. It cannot be that enlightened ministers of the gospel in this advanced century, fail to be convinced of the great risks of the spread of infection and disease from the passing of a cup from lip to lip, but it is the want of courage to give effect to the force of this conviction that stands in the way of the adoption of safer and newer methods. Some two years ago, while discussing the subject of the risks of contagion at the Lord's supper, a very good and zealous minister met the objection in this wise:—"The path of duty is the path of safety." This was the stronghold of his security. In reply we condemned the spirit of charity being manifested so sparingly when one belittles the opinions and fears of others by his own supposed irrefragible reliance on God's power to protect us from physical harm and contamination, even though reason and science (God's gifts to guide us) indicate clearly the danger we are in. Should we thus spurn as it were the guiding lights that Providence has blest us with to discern and avoid harm? DR. ALBERT ASHMEAD, in a recent letter to the *Sun*, writes very much to the same effect: "Of course," he says, "no man who is not a complete survival of the middle ages can assert that, under these circumstances, a man (if he knew) should apply his lips to a probably dangerously contaminated cup trusting in the protection of the Lord, who has allowed hundreds, a hundred times, to perish in burning or earth-shaken churches, while they were in the very act of worshipping Him." Many of those, however, who profess to feel themselves safeguarded by their obedience to duty's call, and their adherence to the path of duty, manifest a lively horror of infection or contagion from those with whom that duty occasionally brings them into contact, as is evident from the following extract from the *Indian Witness*—the organ of non-conformist missions in India—in an issue of not very long ago:—"It would be a great accommodation to persons doing Christian work in the city, if doctors having charge of small-pox patients would have a notice put up. It is a great shock to find yourself unexpectedly in the room of a small-pox patient." If the path of duty be the path of safety, why need the Christian worker be shocked to find himself in the presence of a small-pox patient, and what need is there for medical warnings to him in such circumstances? And is there no cause to be shocked to know that when kneeling around the Lord's table, one is as likely as not, to have the germs of incurable and disgusting afflictions transferred to him or her as the cup is handed round? Small-pox

is a possible disease, but with the cup at the Lord's supper, the risks with their consequences are more certain and terrible. It is a growing faith of the medical profession that the consequences of venereal disease are irremediable. In reference to all other dangerous and communicable diseases, the clergy, and the intelligent portion of the public in general, shew a sensible regard to medical admonition respecting their own safety and that of their brethren; and yet they would ignore professional dictum and advice in the matter of an easily communicable virus, the constitutional effects of which are direful and, what is more, irremediable.

If you would protect the Christian worker in his visits to the sick by medical warnings, why not protect the unsuspecting communicant by some measure which common sense, decency, and sanitation demand?

Apropos of the foregoing remarks are the following incidents related by DR. A. S. ASHMEAD in the *Sun*:—

"The last time I knelt at the communion altar of the Episcopal Church, there knelt at one side of me a patient whom I knew, (as I was treating him at the time), to be a syphilitic; his mouth had mucous patches, which make the disease specially contagious. This person took the cup before it came to me. Of course, I let it pass."

"At another time, the person next to me, but following me in the use of the cup, was also a patient of mine, in an advanced stage of tuberculosis. The mouth of this person was in a condition dangerous to his neighbour."

DR. CHARLES FORBES of Rochester, N. Y., has found in the dregs of a common communion-cup, epithelial cells, bacillar spores and various bacteria, and mucus; while examinations conducted by Drs. HOWARD ANDERS and C. FURNISH, of the dregs of an ordinary communion chalice, revealed tubercle bacilli, pus cells, and abundance of pavement epithelium. Disease-propagating circumstances of the foregoing kind may easily be added to and multiplied, but we think they are sufficient to make any one admit the loathsomeness of the prevalent mode of communion-giving in Protestant churches. It seems very much indeed like tempting Providence in thus persistently exposing thousands and hundreds of thousands, Sunday after Sunday, to direful risks.

Several churches in America are reported to have adopted the more sensible and hygienic practice of providing each communicant with a separate cup; and although on the score of inconvenience and in other respects, this principle may not commend itself to some, or may not be capable of universal adoption, we certainly view the departure from long-established custom with great satisfaction; for the greatest obstacle in the way of effecting a reformation in the matter of administration of the Lord's Supper, is not in any unwillingness to accept a hygienic recommendation, but the desire to adhere to old-standing practices. Writing a few years ago on the matter now under consideration, we suggested that the rim of the cup should be wiped after it has been removed from the lips of a communicant and before it is passed to another; but as more recent observations have disclosed the fact that there lurks serious danger not only in the unwiped rim of the chalice, but also in the wine itself after a few have partaken of it, the single communion cup passed from lip to lip is a source of danger

preceding. Of the total, 10,112 were from suicide; 55,813 were accidental and homicidal; and 23,773 were caused by snake-bites and by wild beasts.

There were 1,361 institutions affording *charitable medical relief* in the different provinces at a cost of Rs. 42,69,861.

The year 1893 was the most disastrous on record. It was attended by the severest epidemic of cholera ever known; and 40,000 or 45,000 pilgrims are reported to have succumbed to the disease, while the smell of putrifying dead bodies is said to have been perceptible sixty miles away. It being the AKBA year, the number of pilgrims was exceptionally large; there was scarcity of food and water, and the season was unusually hot. The average number of pilgrims leaving Bombay was exceeded by about 8,000. India, as usual, is blamed for starting the outbreak; but, as the Sanitary Commissioner of Bombay remarks, there is no ground for this charge against India, as cholera was "at times severely epidemic in parts of the Red Sea Coast, and that some of the villages in the French, Italian and Somali settlements on the Red Sea had been almost depopulated by cholera the previous year."

During the year 1893, investigations were carried on in the laboratory of the Sanitary Commissioner with the Government of India, to test the efficacy of alleged *snake-poison antidotes*, and also on the effects of the habitual use of hemp drugs. The experiments with snake-venom were carried out after the hypodermic administration of minimal lethal doses of the poison. The result of these experiments may be summarised as follows:—Nitrate of strychnine has no effect whatever in preventing the toxic effects of the poison or in preventing death after even minimal lethal doses of the poison have entered the system. Cures reported to have followed the strychnine treatment are therefore accounted for as having occurred in cases in which even less than the minimal lethal dose entered the system.

Saturated solutions of periodate crystals in no way appreciably delayed or modified the development of the nominal toxic phenomena.

A one-per-cent. solution of gold chloride injected either along with minimal lethal doses of the snake-venom or even after the poison has entered the system renders the poison inert; but here the efficacy of gold chloride ceases, as no amount of it introduced when the minimal lethal dose is exceeded, prevents death. It is intended to experiment with solutions of the alkaline hypochlorites, and with the serum of animals rendered immune from the action of the venom as recommended by CALMETTE. Experiments with the poison of RUSSELL'S viper shewed that an essential difference exists between the actions of cobra and viper venoms.

The phenomena resulting from experiments with hemp drugs indicate that the habitual inhalation of *ganja* impairs appetite but reduces *hemorrhages*, so that the habit may be beneficial to those subjected to habitual exertion while unable at the same time to obtain a proper diet.

INDIA'S MEDICAL GRIEVANCES TO BE PRESENTED BEFORE THE BRITISH PARLIAMENT.

THE anomaly of governing a country that is growing under the cruel and crushing weight of financial burdens, verging on the brink of bankruptcy; that highly paid imported labor, while efficient *European* *doctors* *offer* *hand* on every hand, is tantamount to a political crime of the first magnitude. In the medical administration of India, this anomaly stands out in gigantic proportions. We have the European medical services kept at a high numerical standard at enormous cost, whereas military titled officers paid enormous salaries to fill civil appointments and who employ their superabundant spare time in competing on disastrous terms with private practitioners, we have the legitimate and natural aspirations of the people of the soil strangled and smothered and effaced by the perpetual evidence that only Europeans educated in England and employed to serve the State, can ever rise to positions of trust and usefulness, that no man educated in India can ever hope to reach the goal of his ambition and become a leader in his profession by holding a surgeoncy in a hospital or a professorship in a medical school, that even the sacred testimony of independent medical practitioners in India is worthless in the eyes of the State, unless it is supported by the corroboration of some state-paid medical officer.

Under all these impediments and obstacles to her advancement, the local profession has suffered only too long and too patiently, and the time has now come, when a well-sustained and powerfully supported and unanimous representation must be made to the British Parliament. Our voice has been raised almost in vain in endeavouring to obtain the ear of the Indian Government to bestow some little attention to the grievances of the local profession. It is vain and foolish to push aside the consideration of the petitions of a long-suffering profession groaning under a deep sense of its oppression under a galling yoke, by such pleas as "financial depression" and "political complications on the frontier." These excuses do not have a feather's weight when the Government of India finds itself memorialised by the European services of India for exchange compensation, or for an enhancement of the travelling and other allowances of the effeminate officials who shirk their duties in the heat of the plains and flee to the cool retreats of the Himalayan heights for their ceaseless whirl of gaiety and frivolity. No! yet such will continue the reckless and sinful misgovernment of India till the voice of the British Parliament is heard in denouncement of these wrongs, and its hand is stretched out to break the shackles of the oppressed and down-trodden and to set them free. The time has come to reiterate, and India is ready with her prayer to the British House of Commons. The great memorial that the local medical profession will lay at the feet of the real rulers of India—the Commons of the United Kingdom of Great Britain and Ireland—is now ready. This important document, which is to be the *Memorial of the Indian Medical Association*, comes before the Council of the Indian Medical Association immediately, and will be placed in the hands of the people of India in a few days for their approval. More than 1,000,000 signatures for India to the British Parliament has been chosen. It is too premature perhaps

preceding. Of the total, 10,112 were from suicide; 35,618 were accidental and homicidal; and 23,773 were caused by snake-bites and by wild beasts.

There were 1,361 institutions affording charitable medical relief in the different provinces at a cost of Rs. 42,69,881.

The year of 1893 was the most disastrous on record. It was attended by the severest epidemic of cholera ever known; and 40,000 or 45,000 pilgrims are reported to have succumbed to the disease, while the smell of putrifying dead bodies is said to have been perceptible sixty miles away. It being the AKBAR year, the number of pilgrims was exceptionally large; there was scarcity of food and water, and the season was unusually hot. The average number of pilgrims leaving Bombay was exceeded by about 8,000. India, as usual, is blamed for starting the outbreak; but, as the Sanitary Commissioner of Bombay remarks, there is no ground for this charge against India, as cholera was "at times severely epidemic in parts of the Red Sea Coast, and that some of the villages in the French, Italian and Somali settlements on the Red Sea had been almost depopulated by cholera the previous year."

During the year 1893, investigations were carried on in the laboratory of the Sanitary Commissioner with the Government of India, to test the efficacy of alleged snake-poison antidotes, and also on the effects of the habitual use of hemp drugs. The result of these experiments may be summarised as follows:—Nitrate of strychnine has no effect whatever in preventing the toxic effects of the poison or in preventing death after even minimal lethal doses of the poison have entered the system. Cures reported to have followed the strychnine treatment are therefore accounted for as having occurred in cases in which even less than the minimal lethal dose entered the system.

Saturated solutions of periodate crystals in no way appreciably delayed or modified the development of the nominal toxic phenomena.

A one-per-cent. solution of gold chloride injected either along with minimal lethal doses of the snake-venom or even after the poison has entered the system renders the poison inert; but here the efficacy of gold chloride ceases, as no amount of it introduced when the minimal lethal dose is exceeded, prevents death. It is intended to experiment with solutions of the alkaline hypochlorites, and with the serum of animals rendered immune from the action of the venom as recommended by CALMETTE. Experiments with the poison of RUSSELL'S viper shewed that an essential difference exists between the actions of cobra and viper venoms.

The phenomena resulting from experiments with hemp drugs indicate that the habitual inhalation of *ganja* impairs appetite but reduces tissue waste, so that the habit may be beneficial to those subjected to habitual exertion while unable at the same time to obtain a proper diet.

INDIA'S MEDICAL GRIEVANCES TO BE PRESENTED BEFORE THE BRITISH PARLIAMENT.

THE anomaly of governing a country that is groaning under the cruel and crushing weight of financial burdens, veiling on the brink of bankruptcy, by highly paid imported labor, while efficient indigenous talent offers itself on every hand, is tantamount to a political crime of the first magnitude. In the medical administration of India, this anomaly stands out in gigantic proportions. We have the European medical services kept at a high numerical standard at enormous cost, shaming military titled officers paid enormous salaries to fill civil appointments and who employ their superabundant spare time in competing on disastrous terms with private practitioners, we have the legitimate and natural aspirations of the people of the soil strangled and smothered and effaced by the perpetual evidence that only Europeans educated in England and employed to serve the State, can ever rise to positions of trust and usefulness, that no man educated in India can ever hope to reach the goal of his ambition and become a leader in his profession by holding a surgeoncy in a hospital or a professorship in a medical school, that even the sacred testimony of independent medical practitioners in India is worthless in the eyes of the State, unless it is supported by the corroboration of some state-paid medical officer.

Under all these impediments and obstacles to her advancement, the local profession has suffered only too long and too patiently, and the time has now come, when a well-sustained and powerfully supported and unanimous representation must be made to the British Parliament. Our voice has been raised almost in vain in endeavouring to obtain the ear of the Indian Government to bestow some little attention to the grievances of the local profession. It is vain and foolish to push aside the consideration of the petitions of a long-suffering profession groaning under a deep sense of its oppression under a galling yoke, by such pleas as "financial depression" and "political complications on the frontiers." These excuses do not have a feather's weight when the Government of India finds itself memorialised by the European services of India for exchange compensation, or for an enhancement of the travelling and other allowances of the effeminate officials who shirk their duties in the heat of the plains and flee to the cool retreats of the Himalayan heights for their ceaseless whirl of gaiety and frivolity. Not yet such will continue the reckless and sinful misgovernment of India till the voice of the British Parliament is heard in denouncement of these wrongs, and its hand is stretched out to break the shackles of the oppressed and down-trodden and to set them free. The time has come we reiterate, and India is ready with her prayer to the British House of Commons. The great memorial that the local medical profession will lay at the feet of the real rulers of India—the Commons of the United Kingdom of Great Britain and Ireland—is now ready. This important document, which is to be the *MANTRA CHARYA* of the local profession, comes before the Council of the Indian Medical Association immediately, and will be placed in the hands of the people of India in a few days for their approval. More than this, the DELEGATE FOR INDIA TO THE BRITISH PARLIAMENT has been chosen. It is too premature perhaps

yet, as we all stand firmly on a reputation that is based on his genius, energy, enthusiasm, patriotism, public confidence, and a perfect knowledge of the great cause he gave birth to, we expect. The declaration that such an energy has been found, ready and willing and efficient, and that all the needed funds are now at his command, will send a thrill of jubilation and encouragement through every medical heart in India. To us it seems that the early gleams of the sunshine of the great day of medical emancipation are plainly visible in the horizon, and that the shouts of victory for India are being heard along the land.

Let us gird up our loins and stand shoulder to shoulder in the conflict. Let there be no dissensions nor cliques. Let there be no traitors among us seeking to sell our noble heritage for a pultry mess of official pottage. Let us stand together boldly, conscious of our united strength, and of the justice and righteousness of our cause, fully confident that as a profession we have an inalienable right to earn our bread and to exercise our calling ON EQUAL TERMS, without fear or favor, with every imported Britisher who ventures to earn his fortune in India under the fostering care and tender regard of the Indian Government. Let all be ready at the word of command to support the public meetings that will soon be held all over India for the acceptance of the memorial to Parliament, and let every member of our profession take part in such meetings and demonstrate his sympathy by his presence.

In conclusion, we seriously commend the articles in our correspondence columns to our readers. DR. HART's utterances therein are encouraging, while the able handling of his subject by DR. BAHADHURJI will afford much pleasure and inspire enthusiasm, and as will be seen in the "official" pronouncement, we are not altogether without friends among honest officials in our profession; men who will not and cannot accept the CREDO of the official bureaucracy of this land, that "INDIA MUST BE GOVERNED BY OFFICIALS FOR OFFICIALS."

COMMENTS AND NEWS.

THE TREATMENT OF DIPHTHERIA BY ANTITOXIN.

IN the discussion on the treatment of diphtheria by antitoxin raised at the Clinical Society of London by DR. WASSERHOVEN, GOODALL and CARD, it was interesting to note that, among minor differences of opinion, there was general agreement that not only statistics but clinical experience give no undoubted evidence as to the value of the antitoxin serum as a therapeutic agent. Statistically, DR. GOODALL has been able, in a striking manner, to bring down his case-mortality to a lower point than has ever previously been reached in the history of the hospital to which he is attached, whilst others reported similarly.

Erythematous rashes and pains in the joints.—These occurred in 20 per cent. of DR. GOODALL's cases, but they are to be regarded as of no great moment. They are only temporary, and occur most frequently in those cases where large quantities of comparatively inactive serum are given, disappearing in proportion as smaller quantities of more active serum are used.

The desirability of obtaining the antitoxin concentrated and apart from its serum was insisted on, but DR. BRIS WOODHEAD pointed out the extreme difficulty in being able to

separate such a stable and probably physically unstable substance from the "normal" fluid in which it is held in the blood.

Another point raised in discussion, which however was not in agreement with the observations of ROTZ, MARTIN and CHAILLON, was that the most fatal cases were those in which almost pure cultures of the diphtheria bacillus were obtained. It is interesting to note that this has not been the experience of all observers in England either. It is a point that can only be determined after much careful and accurate study of the disease in all its various aspects.

Tetanus and diphtheria.—The different results obtained in the treatment of each of these diseases by the antitoxic serum are exceedingly suggestive. The facts observed and the opinions now held are that the specific effects of the antitoxin are much more definite in the early than the late stage of diphtheria. The suggested explanation for the reason of this, given by DR. WOODHEAD, is that the difference between the two diseases appears to consist in the fact that the primary local lesion of diphtheria is recognisable at an early date, before the general (constitutional) toxæmia has far developed.

In tetanus, on the other hand, before it can be recognised as a disease, the conditional or general condition which follows the local injury and inoculation has developed.

The secondary symptoms of diphtheria correspond really to what we are accustomed to look upon as the real disease in tetanus. It is during this stage of the disease that comparatively little benefit can be given to the patient by the antitoxic serum method. Yet even here, as in certain cases of tetanus, some good may be done by a careful and judicious use of the antitoxin.

EXAMINATIONS FOR THE TRIPLE SCOTCH DIPLOMAS.

THE following questions put at a recent final examination for the diplomas of L.R.C.P., L.R.C.S. Edinburgh, and L.F.S.S. Glasgow, will give our readers a fair idea of the thoroughly practical nature of these qualifications:—

Medicine.—1. What are the two varieties of angina pectoris? Mention the forms of heart disease in which angina pectoris is most common, and give a full description of a paroxysm. 2. What are the causes, symptoms, physical signs, and consequences of spasmodic asthma? Describe an attack. 3. Give the causes, symptoms, and course of pseudo-hypertrophic paralysis. 4. Give the causes, symptoms, and course of diphtheria. In what various ways may it prove fatal?

Surgery.—1. Mention the varieties of tumour of the thyroid. Give the diagnosis and treatment of cystic goitre. 2. Describe the varieties of nevus, and give the treatment which you consider to be most appropriate to each. 3. Name the various dislocations of the shoulder joint. Give the symptoms of the most common form, and describe the method you would employ for its reduction. 4. Give the varieties of whitlow, their pathology and treatment.

Surgical Anatomy.—1. Name the bones of the tarsus in order. Mention all the structures cut through in an operation for the removal of the os calcis. 2. Give the course and relations of the external iliac artery.

Therapeutics.—1. Describe how you would treat a patient threatened with cardiac asystole, as shown by extreme cyanic dyspnoea, feeble and irregular pulse, etc. 2. Give the appropriate treatment—(1) for the night sweats; and (2) for the diarrhoea or advanced phthisis. 3. How would you treat a case of acute catarrh of the stomach produced by alcoholism?

Prescriptions.—Prescribe a mixture containing digitalis and squill for a case of mitral disease of the heart with bronchitis.

Midwifery and Gynaecology.—1. Mention the principal causes of abortion, and describe the treatment of a case of threatened abortion at the third month. 2. State the diagnosis and treatment of presentation of the shoulder. 3. Describe the mechanism of spontaneous evolution. 4. Name the principal displacements to which the uterus is liable. Give the symptoms and treatment in each displacement.

Medical Jurisprudence and Hygiene.—1. Mention the circumstances which, in a dead body, modify (a) Cooling, (b) Rigor Mortis, (c) Putrefaction. 2. Distinguish between an anti-mortem and a post-mortem burn? What are the causes of death after a severe burn? 3. Describe the symptoms, treatment, and post-mortem appearances in carbolic acid poisoning. Give two tests for the detection of the acid. 4. What is meant by "Death rate," and how is it stated? Mention some of the causes which tend to increase the mortality in unhealthy districts.

ADVERTISING PURE AND SIMPLE AND ADVERTISING AS A FINE ART.

ADVERTISING is strongly condemned and rightly so. In Great Britain a doctor who advertises is held up to public censure and often punished. In England hospital medical officers are forbidden to affix their names to any notifications of the appointments of the hospital staff. This too is fair to juniors and struggling practitioners outside the pale of hospital surgeo-nics and physicianships.

Speaking of such medical men advertising themselves through secular channels, the *New York Medical Record* says: "The old way is often criticised, and is not perfect. The man must become known through his work. The profession is not so dull but that it can recognise merit, and it estimates a man's abilities fairly well by his writings and by contact with him in scientific and other meetings. The recognition thus gained comes slowly, but special skill also is acquired slowly, and matters adjust themselves with a good degree of equity in the end."

In India things are very different. Government doctors are all fully advertised by the state in its *Gazettes* and by the lay press which freely copies the *Gazettes*. The hardship of this form of fine art advertising comes in when it is remembered that Government doctors—with few exceptions—compete in general practice with private physicians. Referring to the high salutin of the *New York Medical Record*, the *American Lancet* says:—"This is sound in theory, and we wish it were followed by the leaders in the medical profession. If it were, it would be less difficult for the rank and file to observe the lines of equity. Personally we believe the doctrine certain to lead to the most successful medical career; but here again the flash-light advertisers make such a glare that large numbers are dazzled by the rapid attainment of large business, and decide to "flash" themselves."

Perhaps our so-called "professors" who compete unmercifully with struggling practitioners, in spite of their huge Government salaries and their onerous duties with hospital patients and "original research" and "teaching," will see something in these remarks to touch up their conscience. But we have been hammering so long at this "game of grab" that we almost begin to believe that conscience is dead to the voice of reproof. Yet for the public good we mean to hammer on at these over-worked, over-paid and over-private-practised military-civil surgeons till a change comes, for come it must.

MEDICAL CHANGES BY THE NEW ARMY REORGANISATION.

The distribution of Principal Medical Officers of commands and districts between the Army Medical Staff and the Indian Medical Service is as follows:—

To each of the four commands, a Principal Medical Officer will be appointed; two will be taken from the Army Medical Staff and two from the Indian Medical Service. Officers of either service will be eligible for any command; but either the Bengal or the Punjab command, a Principal Medical Officer belonging to the Indian Medical Service will ordinarily be nominated.

Personal Assistant to the Principal Medical Officer, Her Majesty's Forces, { If a Surgeon-Captain of the Army Medical Staff Rs. 600.
If a Surgeon-Captain of the Indian Medical Service Rs. 600.

The districts of medical superintendence of Surgeon-Colonels will be distributed as follows:—

PUNJAB COMMAND. Medical Staff.

| | | |
|--------------|-----|----------------|
| Rawal Pindee | ... | Head-Quarters. |
| Birhind | ... | Rawal Pindee. |
| | ... | Umballa. |

Indian Medical Service.

| | | |
|-----------------------|-----|-------------|
| Lahore | ... | Meean Meer. |
| Punjab Frontier Force | ... | Abbottabad. |

BENGAL COMMAND.

Army Medical Staff.

| | | |
|------------------------|-----|------------|
| Allahabad and Nerbudda | ... | Allahabad. |
| Meerut and Bundelkhand | ... | Meerut. |
| Outh and Rohilkhand | ... | Lucknow. |

Indian Medical Service.

| | | |
|------------|-----|-----------|
| Assam | ... | Shillong. |
| Presidency | ... | Calcutta. |

MADRAS COMMAND.

Army Medical Staff.

| | | |
|----------------------------------|-----|---------------|
| Secunderabad and Belgaum | ... | Secunderabad. |
| Mandalay with Chin Hills Command | ... | Mandalay. |

Indian Medical Service.

|------------------------|-----|------------|
| Bangalore and Southern | ... | Bangalore. |
| Rangoon | ... | Rangoon. |
| Madras | ... | Madras. |

BOMBAY COMMAND.

Army Medical Staff.

| | | |
|----------------|-----|---------|
| Poona | ... | Poona. |
| Mhow and Deesa | ... | Mhow. |
| Quetta | ... | Quetta. |

Indian Medical Service.

| | | |
|-----------------|-----|------------|
| Bombay and Aden | ... | Bombay. |
| Sind | ... | Kurrachee. |
| Nagpore | ... | Kamti. |

The administrative medical charge of the Peshawar District will be held alternately by a Brigade-Surgeon Lieutenant Colonel of the Army Medical Staff and of the Indian Medical Service.

THE PHYSIOLOGY OF THE FEE.

"How should the fee be paid?" is a very simple problem over which too much mystery is made and too much delicacy displayed by both receiver and donor. Some patients remember to forget the fee, others put it down on the physician's table and then pocket it on a moment of abstraction, some think it a crime for the physician to expect a fee, while others offer it shame-faciously or with trembling hand as if they were about to do something dreadful, and were afraid or ashamed to let the left hand know what the right was doing; and others tender the fee rolled up neatly in paper; but that this last has been taken advantage of by unscrupulous persons is within the experience of every doctor, and was amply proved at the decease of JESSIE DE LAMBERT (who was very careless about fees) when a number of packets (i.e., fees) supposed to contain rouleaux of gold coins were found to be gold

and which has many small business houses between. As it is difficult to understand why any kind of a necessary or should be considered a necessary business transaction between doctor and patient, the doctor has had a card posted up, in the waiting-room, stating the terms on which he might be consulted; but he took whatever was offered him, except when he thought it "too much." DEPUTYMAN used to ring his bell in a particular way to make his hall porter refresh the absent-mindedness of the departing guest. A man "in possession" used to act as Secretary for BROWN and collect the fees due him. Now as the young physician blushes when he gets a fee, while the old one blushes when he is done out of one, and as a snobbish objection has been raised that "it would be impossible to make a man a lord who had held out his hand for guineas," a contemporary suggests that matters would be simplified and nastiness obviated by the employment of a 'Secretary' corresponding to the barrister's clerk to collect their fees for them. We have tried this method for over ten years and find it most workable.

POISONOUS AND EDIBLE MUSHROOMS.

THERE are but a few kinds of poisonous fungi, yet every season a number of persons suffer to a greater or less extent owing to a failure to discriminate between edible and poisonous kinds of fungi. In most cases of poisoning it is impossible to ascertain positively what particular form of fungus has been eaten, but the species almost invariably proves to be *Amanita phalloides*, *A. pantherina* or *A. muscaria*, which grow in similar localities and often intermixed with the edible varieties from which they can be distinguished by the gills remaining permanently white and not touching the stem which is furnished near its top with a thin ring or fringe, and at the bottom is surrounded by a loose sheath or vulva. The lethal effects of the amanita appear in from 14 to 8 hours after eating the fungus, and are due to *Phalline*, which is a virulent blood poison that differs from other toxalbumins by not being neutralised by heat; but it may be antiloted by strychnine sulphate taken in coffee. The varieties that can be eaten with impunity and perfect safety are the *Agaricus aguratus*, *A. campestris*, *A. clerensis* and *Lepiota procera*. The *Helella crispata* and its varieties are excellent when cooked, but when eaten raw, give rise to poisonous symptoms created by the helvellic acid they contain, and which acid is decomposed by heat. The *Coprinus atramentarius* is considered a great delicacy, but if whisky be taken while or soon after eating it, its poisonous symptoms occur. The mycophagist should therefore bear in mind (1) to always properly cook the fungi he eats, (2) to be careful of the variety he makes a meal of, and (3) never to take strong alcoholic drinks with the meal or within four hours after eating fungi.

HOW TO GIVE PILLS TO CHILDREN.

THE plea of mixing-mixtures being open to the grave objection of the relucit often interfering with the action of the medicine, and though older children can be made to swallow nauseating drugs and gobble down pills with very little trouble, still small children cannot swallow pills without showing their up, and if they contain any ill-tasting drug, they are immediately spat out. Gelsemium is the sheet anchor in most fevers when given in combination with an acid, but it is so bitter that children will not take to it. To obviate this Dr. A. C. BORN has the solution made up with aromatic sulphuric acid in small pills, which he directs the mother to break up, and after mixing it with a little brown sugar to place it upon the child's tongue, and give some water to drink, after the pills are in the stomach. A piece of white chocolate may be given before and after the fragments of gelsemium. The sweet and moist way is a

mother's kiss is through her children, and as it is the mother who build up the greatest part of a doctor's practice at home, Dr. BORN thinks that these physicians, who apply themselves resolutely in agreeable, neat and simple form, will not only survive in the terrible struggle for existence, but also winning for Our Art the reverence and allegiance of every intelligent mother in the land, will receive honest medicine from the borders of quacks who beat her at every step, and in the course of a few years at most, the doctor who prescribes for children large quantities of nauseating stuffs that disorder the stomach and exhaust the family purse, will become obsolete.

WATER IN DIET AND THERAPEUTICS.

DR. B. C. LOVELAND mentions some instances where apparently serious disease was cured by the administration of a tonic and increasing the water consumed by the patient, as he notes that, besides relieving thirst, water is a simple fluid that, acting as a solvent for aliment, aids in the absorption of the food-material which it takes with it on its way to the blood, where it forms a medium for the solution and suspension of the various compounds needed for the nourishment of the tissues and helps the effete materials on their way to the excretory organs, and here again water re-exerts its solvent power in the removal of urea, kreatine, chlorides, phosphates, sulphates and some other materials that the blood has no use for and needs constant cleansing from. If the water becomes deficient, osmosis is impeded to a greater or less degree, the bowels suffer, the digestive fluids become too thick to do their work properly, and according to the natural laws of crystallisation, too great concentration (i.e., insufficient dilution) leads to the precipitation of soluble ingredients to form calculi of various sorts and deposits of a harmful nature in the tissues. Lack of water in the blood predisposes to arterial degeneration, uric acid diathesis and congestions, with their attendant evils, while the retention by concentration by the blood, of excrementitious material, converts the life-stream into a slow poison producing mental depression and other reflex symptoms of a grave nature, and as the great majority of diseases are really due to insufficiency of fluid in the body, the judicious use of water will change the character of the blood and restore the body to a healthy tone.

THE RISKS OF THE MEDICAL PRACTITIONER.

SAYS the *Lancet*:—"A story of the way in which the medical man is frequently victimised has lately been reported from Sheffield. An ingratiating visitor took up his quarters at a well-known hotel and inspired confidence by his demeanour and aspect. Having been seized with severe illness he was for a long time attended by two medical men, and a trained nurse was procured for him. The care and treatment bestowed were successful in restoring him to health; but he rewarded his benefactors by abruptly quitting the town without repaying any of the outlay incurred in his behalf. This exemplifies one of the difficult positions in which a practitioner may from time to time be placed. He cannot conscientiously disregard a summons to attend a stranger whose life may be at stake—the question of his remuneration must even be secondary; but our medical brethren will not wisely in not allowing their benevolence to outrun their prudence in the case of obliging patients." Doctors in Calcutta experience this kind of sharp practice very often from "theatricals" and hotel visitors. A good plan is to demand fees in advance, as lawyers do in all cases, from globe-trotting theatricals and their gnomes.

THE PAPAYA TREE.

THE fruit, juice and leaves of the papaya or pawpaw tree, common to most southern latitudes, exerts a solvent action on animal tissue, whether alive or dead, and have been exhibited

Mr. Rankin comments that the chemical test of the purity of water is cumbersome, costly, and of little use; whereas the bacteriological test is easy and accurate.

An excellent speaking for a natural Honorary Surgeon or Assistant Surgeon is said to exist at Pondicherry. There is now an English medical officer in the Colony.

Dr. Daniel Hack Tuke, M.D., F.R.C.P., the great London authority on psychology, died on the 5th March 1895, aged 68 years.

Sir William Roorell Mayors, Baronet, F.R.S., F.R.C.S., consulting surgeon to St. Bartholomew's Hospital, London, died on 4th March 1895, aged 69 years.

I. M. S. Congress wallahs are much offended at Mr. Ernest Hart's acting school master over them. They are abusing him in the *Englishman*.

Surgeon-Colonel James Cleghorn, M.D., is appointed to be Surgeon-Major-General, *vice* Surgeon-Major-General W. R. Rice, M.D., C.M.I.

We regret to hear that Surgeon-Colonel H. Harvey, D.S.O., lately appointed Principal Medical Officer, Punjab Army, is ordered home immediately owing to ill-health.

An epidemic of fever at Rangoon is attributed by Dr. Johnstone, of the General Hospital there, to the putrid water supplied by the Municipality.

We regret to hear that Surgeon Lieutenant-Colonel Wright, who won the D. S. O. in the Upper Burma Campaign, has been compelled to take sick leave home.

Miss Kate Bonnar has obtained a scholarship from the Naini Tal Diocesan High School granted by the Dufferin Fund, and has entered on her medical studies at Lahore.

Deputy Surgeon-General C. J. J. Jackson of Bengal (retired) died at Kise on the 16th January 1895, aged 64 years.

Surgeon-Major A. Milne, Calcutta Mint, is transferred to Bombay as Deputy Assay Master.

Medical leave has been stopped in view of the impending Chitral expedition.

Surgeon-Colonel G. C. Ross is appointed to be Inspector-General of Civil Hospitals, Bengal.

Dr. W. B. Palmer, the talented Editor of the *Medical Age*, died on the 4th January 1895.

The public dinner given to Surgeon Major-General Rice, was a great success. A large body of officials were present.

The man who is perfectly proportioned weighs exactly thirty and three-quarters pounds for every foot of his height.

Miss Alice Van Ingen, M.D., intends to practise in Hyderabad.

Assistant Surgeon C. A. Lafrance has been appointed Second Surgeon of Utica and for six months.

Malaria in an epidemic form is raging in Calcutta.

OUR LONDON LETTER.

(From our own Correspondent.)

For many days past, the intense cold has caused great privation among the poorer classes in London and elsewhere. Many nights and in the early morning Negretti and Zambra's thermometer has registered 10 degrees below zero, i.e., 42 degrees of frost, and this has occurred during many nights. Numberless accidents have happened owing to the glassy condition of the ice-bound roads, and many people have been unable to obtain water, except from plugs derived direct from the great water mains. Consequently but little water is available for flushing drains, and general sanitary condition is very bad; the consequence could readily be foreseen. Although there is decrease of diphtheria, there is a marked increase in the number of fever patients admitted to the hospitals of the Metropolitan Asylum's Board. Cases are recorded of poor creatures frozen to death while seeking for work, food, and shelter. Cabmen have been frozen on their boxes; and policemen, while on duty during the terrible nights of prolonged frost. Numberless cases of frost-bite are reported from different quarters. Suicides and murders have been frequent. One of the dailies has started a fund in order to provide one meal a day for thousands of poor people in the East End and other poverty-stricken localities. Another sign of the severity of the weather we have been enduring, is that flocks of sea-gulls have appeared on the Thames as high as Westminster Bridge. The thermometer now stands 17° F. below zero. The river Thames has been frozen over, and was crossed by a horseman at Kingston. The poverty and distress throughout the great metropolis are perfectly heart-rending. Thousands are out of work; many kinds of business are quite at a standstill. We have counted 13 deaths detailed in one evening paper from the intense frost.

A medical contemporary draws attention to the fact that many practitioners still practise the so-called "open" method of giving chloroform, with a large increase in fatality: recurring to Dr. SNOW's remarks of yore that the anæsthetic should be given in a very diluted form (i.e., with about 5 per cent. of atmospheric air). Dr. LAZARUS demonstrated this at the London Hospital in the course of the year. Still, the number of deaths attributed to this anæsthetic are a reproach to British therapeuticians. As to the treatment of collapse, the sooner the old-fashioned ether injections are discontinued, the better: much more scientific is the hypodermic injection of a tuboid of strychnine sulphate dissolved in a few drops of water and repeated if necessary, with artificial respiration combined.

The last development of Medical Aid Associations is that it is the custom for insurance societies to offer to give to those who insure their lives with them, the additional benefit of medical attendance gratuitously, the Company paying the doctor a yearly stipend. It really seems astonishing that medical men should have concurred with a growth in their midst.

Thyroid Gland Substance is also in vogue. In answer to a paper read by GRAY, M. GRASER stated he had treated three patients (cases) with this substance, and succeeded well in two of them. At the Augusta Hospital, Cologne,

THE INDIAN MEDICAL ASSOCIATION.

ESTABLISHED AND REGISTERED 1894.

REGISTERED OFFICE AND LIBRARY:

150, Dharamtala Street, Calcutta.

TERMS OF MEMBERSHIP

Every man or woman, who being duly and legally qualified to practice medicine, by virtue of holding a degree or diploma or qualification in medicine, whether British, Indian, Colonial, European or American, whether from State Institutions or Independent Medical Schools, and every person holding a Government Certificate entitling such person to practice Medicine in any official or private capacity, shall be eligible for election to Membership in the Association.

Every person desirous of becoming a member, shall send an application in writing in the form in the Schedule below to the Secretary at the Office of the Association, and the Council shall consider and dispose of same at their next meeting. On any person being elected a member an intimation to the effect shall be notified in the journal of the Association, and on payment of the subscription a certificate of membership shall be issued.

(SCHEDULE)—Application for Admission and Agreement as to terms of Membership.

I, _____, residing at _____, am desirous of being elected a Member of the Indian Medical Association; and I agree to pay the subscription, and to conform to the Rules and Regulations now existing, or which hereafter may be made by virtue of the same.

Name..... Address.....
Professional title..... Date.....

Every Member shall pay a subscription of five rupees per annum to the Association, which shall entitle him to all the privileges of Membership. The subscription shall be considered due in advance on the 1st January in each year.

Subscriptions should be forwarded to the Treasurer.

Any Member whose subscription shall not have been paid on or before the 31st December of each year, shall be suspended from all privileges of Membership, and shall not be re-admitted until he shall have paid all arrears.

The Association Journal.

The *Indian Medical Record*, now published fortnightly in Calcutta, shall be the Journal of the Association, and shall be considered the medium of communication between Members of the Association. In it shall be inserted the Transactions and Proceedings, and all notices of meetings of the Association, and any other business which the Council deem necessary.

Officers and Council:

President:—Lal Madhab Mukerji, Rai Bahadur, L.M.S., F.C.U., Principal, Calcutta Medical School.

Vice-Presidents:—(1) E. W. Chambers, L.M.S., L.S.A. Lond., H. M.'s. Coroner for Calcutta.

(2) H. H. Sir Bhagwat Singhjee, K.C.I.E., M.B., C.M., Edin. M.R.C.P., Lond., LL.D., D.O.L., Thakore Sahob of Gondal, Kathiawar.

Members of Council:—Representing Bengal and resident in Calcutta (4 members).

1. H. W. Jones, M.D., M.R.C.S., Eng.

2. Money Lal Dutt, M.R.C.P., Lond.

3. J. G. Anderson, G.M.C.B.

4. K. G. Sircar, M.B., L.M.C.P., Edin.

Representing—

5. **Bombay.**—F. Arthur Foy, M.B., C.M., Edin.

6. **Madras.**—C. G. B. Naylor, M.R.C.S., L.M.C.P., Lond.

7. **Central Provinces.**—Mirza Karim Khan, M.B., C.M., Edin.

8. **Punjab.**—Professor C. C. Caleb, M.B., M.S.

9. **N.-W. P. and Oudh.**—John Morton, M.D., L.R.C.P. & S. Edin.

10. **Burma.**—Surgeon-Major Godber, I. M. S.

11. **Independent Native States.**—A. Mitra, Rai Bahadur, L.R.C.P. and S. Edin.

12. **Assam.**—A. F. McCabe-Dallas, L.M., Dub., L.R.Q.C.P.I.

Treasurer.—Surgeon-Capt. H. C. Hodgkins, S.A.S., Medical College, Calcutta.

Secretary.—James R. Wallace, M.D., L.R.C.P., L.R.C.S., Edin., Editor, *Indian Medical Record*.

Solicitors.—Messrs. Dignam Robinson and Sparkes, Attorneys-at-Law, High Court, Calcutta.

Bankers.—Messrs. Grindlay and Co., Calcutta.

JERGO

MELODIES

"Chunar's Rock and Battled Tower"

BY

J. L. RAWLING SMITH

Warrant Medical Officer, Bengal Medical Service.

DEDICATED TO THE

Warrant Medical Officers of India

As a slight token of respect and esteem by their humble friend the author.

Price :—Inclusive of postage, eight annas, which must be sent in postage stamps with the order to the MANAGER, "Indian Medical Record."

Every Warrant Medical Officer should spare eight annas to encourage and help a literary venture by one of their own service men.

N. B.—As only a few hundred copies of the 1st Edition of Jergo Melodies are printed please apply early for a copy.

25 patients were treated; result, 22 of these stout individuals lost a satisfactory amount of superfluous adipose tissue.

We regret to record the sad demise of Mr. WHITEFIELD of Bristol, who, driven to desperation through being unable to meet his liabilities, took a dose of hydrocyanic acid. He leaves behind a widow with several young children in a state of deplorable destitution.

The report of Drs. G. SIMS WOODHEAD and E. C. WOOD, detailed in our renowned contemporary, *The British Medical Journal*, condemns filters as a whole, as being quite useless protectors against water-borne germs; excluding only three kinds which proved to have any effect in safeguarding against these ravages, viz.:—(1) The Pasteur-Chamberland Filter; (2) Berkefeld Filter Company, Limited; (3) the Aéri-filtre Maillie Porcelaine D'amianto Maison Maillie (Paris).

At a meeting of the Midland County's branch of the B. M. A., Mr. CHRISTOPHER MARTIN shewed a case of spurious hermaphroditism. A person aged 21, with external genitalia and characteristics of a woman, but the essential organs of a man, had been brought up as a woman and had earned his living as a nursemaid, kitchen-maid, and barnmaid. In February 1894 he had a painful swelling in left inguinal region. Mr. MARTIN cut down upon it and removed an undoubted testis. In October 1894 Mr. MARTIN again operated on a painful lump in the right groin, thus removing the other testicle. There was no trace of beard, whiskers, or moustache. Breasts were flat and poorly nourished; no hair on external genitals. There were labia majora and minora, a vestibule with meatus urinarius, small clitoris, vaginal ostium with hymen, vagina, a cul de sac 1½ inch long, with no trace of a uterus. When first testis was excised, hair began to grow on pubes, and he developed symptoms of hysteria; after the second testicle was ablated, breasts became enlarged and tender, at the same time he complained of "heats and flushes" common to the "climacteric."

Bradford Medico-Chirurgical Society.—Dr. CHAPMAN shewed a child suffering from sporadic cretinism, who was improving under the thyroid gland treatment. At a meeting of the *Sheffield Medico-Chirurgical Society*, Dr. BARNARD STEDMAN read a paper on "Rectal Etherisation," in the course of which he stated that he had administered ether per rectum in about 20 cases of operations about the mouth at the Sheffield Public Hospital, and that so far his results had been very satisfactory. His plan consisted in placing a vessel containing ether in water at a temperature of 120°F., and then conducting the vapour through India-rubber tubing into the rectum. There was little or no struggling during the administration. Its disadvantage was that it sometimes took half an hour to anaesthetise the patients. After this was done, the temperature could be reduced to 110°F. This practice was sufficient, when anaesthesia had been accomplished, to keep the patient under its influence. That also after-effects in his cases were slight. In half the cases no sickness; in 2 or 3 a little diarrhoea with mucous discharge; no pain in rectum complained of.

At a meeting of the *Leicester Medical Society*, Dr. MACKAY read case-notes of a patient afflicted with myxodema treated by thyroid gland, and practically cured. Dr. WILKIN BLAKE read notes of two cases of pericels

treated by thyroid gland; the first was cured; the second after shewing marked improvement, relapsed. Dr. KEAY treated two cases of insanity with the same drug, but his results were negative.

At Sutton Coldfield an obscure outbreak of disease was attributed to soup; 18 gallons of this were given away to poor people, and within 48 hours 100 or more of these folks were attacked with vomiting, purging and prostration. Samples of the food were analysed by Professor HALL, and no trace of any mineral poison was detected; saltpetre was suggested but vetoed by the analysts. There was in every case, swelling and pain in the abdomen. One patient has died; sewer gas has been suggested as the cause of the poisoning. There has been an attempt made lately by numerous medical men to establish the operation of castration as a cure for prostatic hypertrophy.

It is reported that Mr. JOHN OGHILY of Inchilewan (Forthlirre) who died early in the year, aged 100, though a qualified medical man, did not practice.

The *S. S. Heron*, on arriving at Gravesend, reported that an A.B., while the ship was at Massena, was attacked with cholera and died in 38 hours. The body was cremated on shore at Port Augusta.

The British Massage Association is now an established fact.

There has been a deal of discussion lately on hospital abuse. Here is just an anecdote that may prove interesting. A patient in the garb of the church applied for admission to one of the northern infirmaries, as he complained of a mysterious cutaneous eruption. The surgeon who saw him said that a man in his position should not apply to a hospital for relief. On his stating his inability to pay a doctor, he was admitted to the ward set apart for venereal diseases. The surgeon going round with his class entered this particular ward and approached the bed allotted to the clergyman, who, on observing the surgeons following, thereupon divined under the bed-sheets, completely enshrouding his countenance. The surgeon omitted for the time to examine him through courtesy, but shortly after ascertained, that among the body of students who attended him on his visitation, the cleric in question was startled to observe the countenances of two nephews, and further, he was discovered to be anything but the pauper he affected to be!

We hear that the organisation of the next International Medical Congress, which is to meet in Moscow in the year 1897, has already commenced, the Executive Committee having for their Chairman Dr. KLEIN, Professor of Morbid Anatomy in the University.

A prize was offered for essays on various points, chiefly connected with prevalence, etc., of leprosy about a year ago. Ten questions were propounded. The *Lancet* says that no fewer than ten essays have been sent in. The adjudicators have amongst them Sir J. FAYRE, Sir GREYS HUNTER, and Mr. JONATHAN HUTCHINSON, who state that all the essays shew great insight into the subjects discussed. It is expected that a decision will be shortly announced, and that the selected essays will be published if the funds permit.

Dr. BARKS (Leeds) reports a case of pernicious anaemia cured with marrow substance after iron had totally failed, and the amount of arsenic administered had produced

prophylaxis. Dr. Fabry reports a case of cholera treated successfully with red nervous tablets (B. W. & Co.)

A new medical journal has struggled into birth amongst us, entitled *Clinical Sketches*; its Editor is Norman SMITH, F.R.C.S., & Imperialis well, and is fortunate in securing among its contributors, Mr. J. B. BOTTEN.

Mr. James Macnair, M.B. (Northampton) records a case of traumatic arthritis treated with injections of tetanus antitoxin, the total amount injected being over 9 grammes, and the patient being cured by the treatment in 15 days.

J. LLOYD FIRTH, M.D., M.S., F.R.C.S., gives notes of a case of *tetanus neonatorum* (often seen in India) unsuccessfully treated with tetanus anti-toxin; his doses were too small, hence perhaps the untoward result of the treatment, although the malady is a rapidly fatal one as a rule. The smallest dose injected should be from 1 gramme upwards to 2 or 3 grammes. The treatment of diphtheria by anti-diphtheritic serum is still scoring numerous successes, although violently, and somewhat unscientifically opposed by some medical men.

We regret to record the death of JOHN WHITAKER HOLKE, F.R.S., F.R.C.S., late President of the Royal College of Surgeons, England, Senior Surgeon to the Middlesex Hospital, etc., and an active Fellow of the Geological Society. He was an old Cretan Surgeon, and also served in the West Indies. We note the fact that he always exhibited the greatest kindness towards his pupils, many of whom owe much of their success in life to his influence and teaching. The cause of his death was *post-influenza pneumonia*, at Old Burlington Street, London, on 26th February 1906. His death is deeply regretted by all who knew him. He took part in one of our latter-day discussions on the subject of "Yaws" (Framboesia) and was the author of well-known surgical works.

Current Medical Literature.

MEDICINE.

Prophylaxis of Malaria: the best forms of Quinine to administer.

THE Societe de Therapeutique recently appointed a committee (MM. Adrian, Barlet, Berlios, and Boymond) to report on the above question. The Commission concludes that the employment of solutions of salts of quinine should be reserved for active attacks of malaria. The best prophylactic salt of quinine to use is the basic hydrochlorate, it being the richest in alkaloid and sufficiently soluble. It has a less irritating action on the stomach than the sulphate. The hydrobromate should be used only in cases rebellious to the hydrochlorate. As to the pharmaceutical form in which the hydrochlorate should be administered, compressed preparations are recommended, and pills made up with a soluble excipient or *perles* provided with a gelatinous envelope are recommended. *Pills or perles* containing each fifteen centigrammes of the chlorhydrate and given one in the morning and one at night, or else, before meals, suffice to keep the system under the influence of quinine so as to ward off attacks of fever. In the course of the discussion following the reading of the report, it was suggested that the War Office should be urged to desist from its attempt to manufacture on a large scale compressed tablets of quinine for the use of the troops, being that the report was unfavorable to that method.

A severe case of Multiple Sclerosis.

IN a recent number of the *Neurologische Klinische Wochenschrift* there appeared an abstract of an interesting case gathered by Professor LEBERT in the *Städt. Klinik, Strassburg*. The patient was a woman twenty-seven years of age, who had been ill since the commencement of 1892. She came under observation in May 1893, and at that time was in a most helpless condition. She was unable to move her extremities, and could not raise herself or sit upright. Her memory was much impaired, and she was forgetful and emotional. The extensor groups of muscles were much wasted, the knee-jerk was absent, and conduction of painful impressions was delayed. The patient was much wasted. No disease came could be found to account for the condition, and Professor LEBERT regarded the case as probably one of rheumatic multiple neuritis. On account of the extremely severe character of the disease, the prognosis was somewhat doubtful, but energetic treatment by means of gymnastic exercises, electricity, and strychnia injections was in the course of ten months effective in completely restoring the patient to health and activity.—*Lancet*.

Treatment of Infantile Convulsions.

JULES SIMON, who agrees with most observers that these symptoms are due to digestive disturbances, directs his attention to the alimentary canal which he promptly clears by a warm clyster of oil or glycerine, a teaspoonful or two at a time, and if the stomach appears to contain undigested food, he orders an emetic. After the bowels have acted, he prevents recurrence of the convulsions. He employs rectal injections of chloral and milk, and the hourly internal exhibition of small doses of bromide of potassium. Cutaneous revulsives, such as hot baths, mustard baths and blisters to the nape of the neck he never uses, except in obstinate cases, as he prefers—if the bowels are late in acting—Chloroform to control the spasms. He urges the necessity for immediately searching for the cause of the convulsion, which may be due to cutaneous irritation, uremia, or reflex irritation from phimosia, hernia or foreign bodies in the ear, if constipation, indigestion or inflammatory disease of the bowels are absent, and such symptoms must, of course, be promptly attended to and relieved.

A new Sign of Diabetes and Albuminuria.

M. GAREL of Lyon claims to have discovered a hitherto unrecorded physical sign which is almost pathognomonic of either diabetes or albuminuria. He states that many patients complain of a slight irritation of the throat—some difficulty of deglutition, a sensation of swelling, and constipation of the faeces. The soft palate, the pillars, and the posterior wall of the pharynx are found to be red and swollen, and frequently covered with a more or less viscid layer of mucus. In the majority of such cases, examination of the urine reveals the presence of either glucose or albumen. Most of these patients present only quite insignificant general symptoms, so that M. GAREL's discovery, if it be confirmed, is of considerable value. Of twenty-one individuals affected with this particular form of pharyngitis, ten had diabetes and eleven albuminuria, and in three of the cases sugar and albumen alternated in the urine. I would, however, ask if it be not the wiser plan to analyse, as a matter of routine, the urine of every new patient, more especially when middle age has been reached? In my own practice I think it better to do so, and I have therefore taken a *Simms* pharyngeal speculum.

Chloroform Test for Urinary Diabetes.

YAMAGUCHI reports a case of diabetes in which the test for glucose failed, when applied to the specimen, but was struck down with accuracy and speed on the third day.

...the patient was found to be suffering from a severe attack of gonorrhoea, from which he was cured. He had a second day that had lasted five months, when he suddenly got an attack of left hemiplegia which, however, cleared up, but showing evidence of cardiac lesions or of arteriosclerosis, caused considerable awkwardness in the voluntary movements of the left hand, and the fact that vegetative is frequently a result of gonorrhoea, would suggest that these cerebral lesions have a close casual connection with that disease, and are not merely coincidences.

The forms of Diabetes.

DR. GEORGE HARLEY gives the following classification of diabetes:—

1. Hepatic diabetes—including the gouty variety.
2. Cerebral diabetes—including all cases of saccharine urine arising from nerve derangement.
3. Pancreatic diabetes—the most deadly form of the disease.
4. Hereditary diabetes—a form by no means uncommon, and one, too, where both brothers and sisters may labor under the disease without either their maternal or paternal parent having been affected by diabetes, though more distant members of the family may have suffered from it.
5. Food diabetes—including all forms of saccharine-urine arising from the ingestion of unwholesome substances.

In the matter of treatment, besides diet and opium or colicin, Dr. Harley recommends croton, chloral, strychnine, phosphoric acid for thirst, and an absolute prohibition of alcohol.—*Amer. Lancet.*

SURGERY.

Castration in Hypertrophy of the Prostate Gland.

PROFESSOR WHITE was the first to suggest this operation for the relief of enlarged prostate. SIR HENRY THOMPSON has pointed out, after careful observation, that one man out of every 8 over 64 years of age has enlargement of the prostate; 1 out of every 7 presents some amount of obstruction; while one out of every 13 has sufficient enlargement to call for some form of treatment. The lives of such patients are usually threatened and undermined by retention, backward pressure of urine on the kidneys, and the frequent use of the catheter. Loss of sleep is thus entailed, also because of the incessant demand at night to void urine. The methods usually adopted therefore have been the various forms of prostaticotomy. The *extra-perineal* method is often attended with pain, failure and a high mortality. The *perineal* form is dangerous owing to the free hemorrhage that follows, and at best it is only a palliative method of treatment, doing good only temporarily, but entailing the use of a bougie, and confining the patient to bed for many weeks.

Combined supra-perineal and perineal prostatectomy enables the gland to be excised with greater freedom, but it is an operation of such gravity as to be more indicated in the very cases which are destined to benefit. In view of these facts it is not surprising that castration has been resorted to by surgeons as a palliative method of treating enlarged prostate. That was its indication at a period when the water was

right to become fossilized and as when the only means of relieving suffering for many months and years, as he related only by death. Unmistakable objections to that of securing permanent relief, without placing the life of the patient in danger, pale into insignificance.

There have been recorded from America, Norway, Sweden and England in all 18 cases of castration, all of which have been more or less successful, and there have been, of course, no deaths. The least favorable cases have obtained relief, certainly greater, than by any other method hitherto employed. The rapid shrinking of the enlarged gland and the simultaneous relief afforded the patient are "truly marvellous." Castration is not indicated in every case of hypertrophied prostate. Cases of prostatic abscess, prostatitis, trichitis of the prostate, and other forms of obstruction in its neighborhood must be clearly distinguished from enlarged prostate. The results have been so uniformly favorable, that castration may now be considered a *specific* for hypertrophy of the prostate.

Gun Shot Wound of the Spleen and Kidney: Abdominal Section: Haemorrhage by deep suture: Recovery.

DR. LOUIS M. TIFFANY, of Baltimore, in a paper given the following details concerning a gun-shot wound in a young Negro, aged 20. He was wounded at the distance of 35 feet by a small-calibre rifle from behind, he being erect. The wound was 3 inches below the spine; and beyond the urine being slightly albuminous, there was nothing else wrong. The patient was anaesthetised, the dorsal wound enlarged and examined. The upper portion of the left kidney was found perforated and dark blood was issuing. On examining the abdomen externally, nothing was elicited, not even pain. DR. TIFFANY, however, opened it freely, suspecting further internal mischief. The peritoneal cavity contained some blood; the intestines were not wounded, but the spleen was found perforated about 3 inches from the free lower border. Blood flowed from both wounds (entrances and exit). Haemorrhage was arrested by deep ligature by means of a long needle, threaded with silk, being passed *entirely* through the spleen central to and parallel with the bullet-track; the long ligature being then tied over the free border of the organ, so as to press the surfaces of the wound together tightly enough to arrest haemorrhage, but without tearing the splenic tissue. The ends of the ligature were cut short, and the peritoneal cavity closed after irrigation; the kidney being tamponed with gauze through the dorsal wound. The anterior wound healed by primary union; urine flowed freely for two days only from the dorsal wound which healed by granulation. The accident happened on 1st March, and the patient was discharged cured, on 22nd April.

Internal Haemorrhoids.

DUNDON, after an exhaustive paper on the subject of internal hemorrhoids, concludes as follows:—

(1). The ligature is the safest method of operating for internal hemorrhoids, as there is less likelihood of its being followed by hemorrhage, stricture, or stoma.

(2). The clamp and cautery causes less pain, shorter convalescence, and is less likely to be followed by retention of urine than when the ligature is used; but hemorrhage and stricture of the rectum may very often follow their improper application.

(3). The practice of WHITMAN's method should be limited to those cases in which the entire circumference of the anus is involved. In ordinary cases of one or more hemorrhoids it should never be used, as it is liable to be

followed by severe after-effects, and at best could produce no more radical result than the clamp and cautery or ligature.

(4). Simple dilatation of the sphincter, injection of carbolic acid, and MAULEY'S method are simple palliatives, and their use is very limited.

(5). There is no single operation which is available in all cases. Experience alone should suggest the most efficient method of treating each individual case.—*Mathew's Med. Quarterly*.

The evils of neglecting Diseases of the Ear.

Few general practitioners having been specially trained to examine the ear, which lies deep within the temporal bone, and the educational process being a slow one, necessitating for its completion the sacrifice of many lives and countless ears, it often happens that failing to realise the results of a neglected otitis media or to differentiate it from abscess of the external ear or other harmless affections, they fondly hope that the disease will cure itself, or that in the case of a running ear the child will outgrow the disease, which had better not (!!!) be smothered with, and until human beings think less of hoarding up money and more of attending to their physical condition, and have their ears periodically examined, it will be impossible to recognise these cases at the time most favorable for treatment, which is necessary at its inception, or as soon as is possible after the diagnosis of suppurative otitis media, has been confirmed, which can be readily cured if taken in time, but if neglected, may lead to destruction of the ear or even loss of life. Deaf-mutism is a common result of suppurative otitis media, which may also be the starting-point as well as the deterrent factor in the treatment of:—Caries, necrosis, deafness, *arria* brain lesions, thrombosis of the lateral sinus, pyæmia, and infection and inflammation of the lungs, liver and other organs.

Treatment of Corneal Ulcers.

MULLA divides corneal ulcers into those of nervous and non-nervous origin. Nerve cases are not included. He cures the non-nervous cases in a few days, without scraping, cautery, or section. Histories of twelve cases were given of infiltrated corneal ulcers with hypopyon in some of the cases, 12/13 in one. The cure was usually complete in three days, with a small nebula remaining.

The treatment consisted of:—First, anesthesia by an 8 per cent. solution of cocaine. Then he applies a thin wafer of iodoform over the cornea and gently closes the lids; these are covered with a pad of iodoform, the whole secured by a flannel roller to give rest and prevent reinfection. After three days no further protection is necessary.

He has employed the same treatment as a preventive to infection after operations, with uniformly good results.—*Lancet*.

OBSTETRICS AND GYNECOLOGY.

Dysmenorrhœa.

PROFESSOR H. A. MULLA, M.D. describes dysmenorrhœa as nothing more or less than pelvic pain at the menstrual period and association with a large variety of diseases of the uterus, tubes and ovaries. In the majority of instances it is caused by small myomata, the presence of which, he thinks, is first discovered by careful rectal examination. He refers to two other types of dysmenorrhœa, the first occurring in girls under 20 years of age, and being associated with a variety of dyscrasia, the most prominent of which is chlorosis and the

other belonging to anæsthetic or hysterical groups, and being sometimes associated with defective development of the uterus and ovaries. Local treatment is almost useless, in it rarely being of value, but claims good results from careful attention to hygiene and regulation of exercise and study. He lays greatest stress on rest in bed, and recommends mild sedatives, hot tea, also in rather full doses combined with myrrh or asafoetida to empty the lower bowel, together with hot hip-baths to accentuate pelvic congestion and hasten the flow; but when serious pelvic lesions endangering life co-exist, he thinks the tubes, ovaries or uterus should unhesitatingly be removed. This latter procedure should also, he points out, be adopted even with healthy organs, to stop painful menstruation, which is wrecking the patient's life.

Scanty Menstruation.

DR. F. TOWNSEND finds that this condition is most usually the result of malnutrition in young and middle-aged women, whether married or single, and attributes it to chloro-anæmia, which must be rectified by intelligent medication, chief in which is iron, after the road has been prepared for its exhibition by the careful administration of salines. He also insists on a correction, as far as practicable, or removal of the "*epêche injuria forma*" such as jealousy, disappointments and other emotions which not only offend the affections, but also are often the immediate antecedents which eventually result in impoverishing the blood by lessening the number of blood globules, and thus becoming the starting-point of serious disease of the lungs and kidneys and many of the zymotic troubles so often encountered. He also advocates electricity as advantageous, and cautions that if a permanent cure is to be expected, persistent patience must be persevered in with the various forms of treatment laid down.

Fatty Heart as a cause of sudden Death during Labor.

MR. H. M. EAMES demonstrates the imperative necessity of insisting upon the recumbent position during the whole time that a person with a weak or diseased heart is in labor. He was suddenly called in to attend a big, stout plethoric woman in whom labor (full term) had set in four hours previously, and for the last couple of hours she walked up and down the room, when she complained of feeling ill. A stimulant having been given her, she appeared to revive, and Mr. EAMES was sent for; at the same time she recommenced her perambulations, the pains continuing at intervals, but just as he entered the door, she fell lifeless on the floor. Subsequent application of ether did no good, turning was not practicable, as the cervix was not sufficiently dilated, and her friends would not permit Cæsarean section.

Pregnancy after Gastro-jejunostomy.

J. MASSIAH having been called in to see a woman aged 38, who was ill with indigestion, diagnosed pyloric obstruction, for which he sent her to the Manchester Infirmary, where MR. WRIGHT performed gastro-jejunostomy for a large pyloric tumour with secondary nodules. As she seemed to grow more and more thin, she was sent to a seaside curative home (7 months later) where she remained for a month. Subsequent to this, she sent MR. DR. MASSIAH, complaining of swelling of the legs and other symptoms that made him suspect she was "*near her end*," but a week later, while cleansing the bath, she felt violent abdominal pains, which so increased, that she was compelled to lie down, when something inside burst. She thought it was "*a wind and water vapour*" left after MR. WRIGHT'S operation; but was surprised to find that she had given birth

the tumor in the early stages of life. The possibility of this tumor is that the "mother" never knew she was pregnant and the tumor was not removed until after the birth of the child. One of the numerous secondary tumors left completely unremoved; but after the birth of the child, the tumor began to decrease, per se and the mother to grow robust and pick up strength, flesh and color, while the tumor pains disappeared.

Strychnine as a Prophylactic in weak Labor Pain.

Dr. Dorr employs strychnine as a prophylactic in decreased muscular tonus and general weakness of pregnant women, as well as in cases giving a history of weak and irregular uterine contractions in previous labors, distinct weakness and flaccidity of the abdominal muscles, and post-partum hemorrhages from faulty contraction of the uterus. He prescribes 1-64 grain of the drug three times a day, commencing six or eight weeks before the date of the expected labor; eight days before the event the dose may be increased to 1-48 and 1-32 grain. The results are claimed to be very satisfactory.—*Pac. Med. Jour.*

Prolapsed Uteri in a Virginal Nullipara.

Dr. M. LIEBMANN records an instance of prolapsus uteri et vaginae in a virginal nullipara of only 17 years of age. Two years previously the patient noticed that something came down in the region of the genitals when she strained at stool or coughed. She consulted a midwife, who gave her a pessary with which to keep up the uterus. Later she came under the author's observation, who found her suffering from prolapsus uteri, and also from phthisis. On account of the latter condition and the severe cough, no operation was performed, but a ring pessary was introduced, which for a time was successful.—*Centralblatt für Gynäkologie.*

A Sign of Breech Presentation.

PINARD asserts that when, in a woman who has passed the sixth month of pregnancy, a sharp pain is produced by placing the hand on the fundus uteri, it may be almost affirmed that there is a breech presentation. The fact is very frequent, although not constant, being present in about 70 per cent. of cases. The pain is sometimes spontaneous, and if version is performed, it disappears. PINARD claims that the pain is due to the "irregular distention produced by the rounded mass of the head," but he does not explain how an irregular distention can be produced by a rounded mass.—*La Clinique Internal.*

Retrosession of a Uterine Fibro-myoma after removal of both Breasts.

HEIDENHAIN relates the case of a patient suffering from a large uterine fibroid which had disappeared seven months after the removal of both breasts for tumours and clearing out of the axilla. The nature of the mammary tumours is not stated. HEIDENHAIN attributes the retrosession of the fibroid to amputation of the breasts, and suggests this operation in certain cases in preference to hysterectomy. The woman was 44 years of age.—*Gazette de Gynecologie.*

Gynecologic Forceps Statistics.

SCHMIDT gives a series of 2,926 deliveries in the Beale Hospital between 1st May 1887, and 31st December 1892, of which number 186 (or 6.42 per cent. of the total) were delivered by the forceps, and of these, 139 (or 63.3 per cent.) were primiparae. Presentation in the second position was the most frequent cause for their use. The loss of blood was

estimated at 400 grams on the average. In 100 cases (5.6 per cent.) the perineum was ruptured, and the wound healed by primary union in 98 cases. The mortality being all there, deliveries was 1.28 per cent., but this was not due to the application of the forceps. The infant mortality was 19.5 per cent.—3.7 per cent. being the result of use of the forceps. SCHMIDT recommends their use when the pains diminish owing to the prolonged labor when the head is in a proper position and when the second stage has lasted more than two and a half hours.—*N. Y. Med. Jour.*

PHYSIOLOGY, PATHOLOGY AND BACTERIOLOGY.

Significance of the Venous Pulse.

Dr. JAMES MACKENZIE divides the venous pulse into two forms: (1) the *auricular*, presenting distinct evidence of functional activity of the right auricle, and ceasing the diastole, decreases, and finally disappears with the increase of the (2) *ventricular* venous pulse, which is a more advanced stage than the auricular, but appears only when there is organic disease of the heart itself as in valvular disease, yet when heart-failure is functional and not due to organic valvular disease, the auricular pulse persists to the very end. Although the disappearance of the venous pulse is sometimes a sign of the return to health, yet in other cases, it precedes a fatal termination, and its appearance, increase, decrease and disappearance give evidence of changes in blood-pressure not appreciable by any signs given by the arterial pulse while, as a general rule, increase of venous pressure implies diminution of arterial pressure, and the appearance of the ventricular wave gives information regarding the degree of incompetence of the tricuspid orifice as also of the exact time of closure of the pulmonary valves. In pulse irregularities a careful study of the venous pulse throws a new light upon the heart's movements and affords the only true knowledge of the action of the different chambers of the heart.

Normal Menstruation.

ANDREW F. CURRIER points out that menstruation, which may occur at any period between 9 and 20 years, is one of the signs of womanhood; still as it is not the only one, the family physician should carefully instruct those under his care concerning the precautions they should exercise during menstruation; for the unpleasant sensations or *melanias* are chiefly the result of undue vascular congestion and tension dependent on climate, altitude, habits, race, and national and family peculiarities, many of which can and ought to be corrected. No satisfactory explanation is forthcoming why menstruation should be so frequent and periodical, or why exhibit such variety of phenomena as it does; but all are agreed that the civilized woman suffers more than does the robust uncivilized one. The duration of menstruation fluctuates a great deal, as the complete period includes not only the flow, but also the *melanias* which precede or follow it and may, in ordinary health, last from 1 to 4 days. The one-day type being scanty, watery, painful in various localities and occurring in anemic or weak women or those whose genital organs are imperfect. The two-day type simulates the one-day, except that the blood may be natural and abundant on the first day, and scanty and watery on the second. In the three-day type, profuse hemorrhage seldom occurs, and the menstrual wave gradually advances and recedes, while there may or may not be pain. The four-day type may be quite normal as to pain and discharge, but the bleeding is usually abundant, the pain intense, and the menses more or less discolored, whereas if the flow is profuse, lasting from 5 to 7 days, serious disease of a local or less serious nature is likely to be present.

Functions of the pituitary body.

YAMALE AND SACCHI point out that the pituitary produces a secretion of profound importance in the nervous and neuromuscular systems, and that the intensity of the symptoms vary according to the extent of the removal of the gland. Main among the symptoms were:—Anorexia, listlessness, fall of temperature to subnormal, progressive hebetude of the animal, fibrillary twitchings and tremors of the muscles, followed later on by cramps and spasms and respiratory spasms (dyspnoea); but in complete extirpation of the gland, many of these symptoms abated if the animal was injected with pituitary extract.

Formation of Urea in the Liver.

FROM a long series of experiments on rabbits, **W. VON MEISTER** concludes (1) that the formation of urea ceases after complete removal of the liver, while the quantity excreted was in direct proportion to the quantity of liver remaining behind; and exhibits a parallelism between the quantity excreted and the growth of the remaining part of the liver. (2) That as far as three-fourths of the liver can be removed without affecting the mortality or inconveniencing the animal, and occlusion of the gallbladder without removing the hepatic duct does not affect the functions of the organism, but complete removal of the liver shortens the duration of life. (3) After removal of one or more lobes, the quantity of nitrogen in the urine diminishes, and the urea decreases relatively as well as absolutely; but the quantity of extractive substances increases in proportion to the decrease of the urea, and the larger the quantity of liver removed, the less the amount of urea excreted. (4) That while urea is undoubtedly formed in the liver, its primary origin is in the extractive substances, and the decrease of the urea is especially rapid during the first days after removal of liver tissue.

Pathology of Insanity.

AFTER due inquiry into the necessity for investigating the pathological and physiological anatomy of the brain, the London County Council has decided to establish a laboratory and appoint a pathologist at each of its lunatic asylums. And the first of its kind is now being built at Clabury Asylum, where the pathologist in charge will be offered £700 per annum. **DR. ALEXANDER** of Hanwell Asylum does not think it possible that any immediate results will be obtained, but **DR. CLAY SHAW**, the medical Superintendent of Banstead Asylum, is more sanguine, and thinks that if the paths of normal brain action are brought into direct relation with diseased processes which requires the special knowledge of the physiologist and pathologist combined, satisfactory conclusions could be arrived at, pointing to great improvement in the treatment and prevention, if not actually the cure of insanity and mental diseases. To this latter opinion incline the majority of the evidence received from brain specialists on the continent.

Bactericidal and Toxic Action of the Blood of the Insane.

As the result of 86 sets of observations made on idiots, maniacs, melancholics, paralytics, and persons with pell-agrous insanity, **D'ABUNDO** found that the toxicity and bactericidal power of the blood diminished in the depressed form, but increased in all other forms of insanity.

PUBLIC AND DOMESTIC HYGIENE AND JURISPRUDENCE.

The disposal of Garbage.

IN 1884 the treasure-chest of the New York City Department of Charities and Corrections was indented on for \$180,000 for the purchase of Riker's Island to which, after reclamation of its submerged lands, it is intended to transfer the penal institutions from Blackwell's Island, the southern portion of which is to be converted into a fine public park, but ignoring the lessons taught by Hart's Island the city authorities proceeded to recover the land by making

the submerged portions the "floating ground" for the New York refuse, and had "made" about 30 acres of land, where there arise such a far-reaching and highly objectionable stench from the rotting garbage that the dwellers on the Riker's Island side of New York threatened "mob law" if the nuisance were not abated. To remedy the nuisance, the authorities have taken advantage of the well-known germicidal and disinfecting properties of the hypochlorites, by erecting four vats, each capable of holding 1,000 gallons of sea-water, and containing a set of four electrodes of platinum and zinc through which passes the current from two dynamos to transmute the chlorides of the sea-water into hypochlorites, which are distributed (by steam pumps) over the refuse, in the form of a spray that has so far deodorized the stench that the authorities contemplate treating their city refuse dumps in a similar way and then conveying it to Riker's Island; but **DR. G. F. SHERRY** raises the objection—and a right one too—that before the refuse of the city can be safely utilised for the purpose of reclaiming submerged land, the putrescible portion of it must be rendered innocuous which cannot be done by any other agent than fire.

Natural Sanitation.

THE natural conditions which should be incident to the life of human beings, conducive to long and healthful life, are:—

- (a). Breeding from parents free from physical or mental taint.
- (b). Feeding the infant upon the mother's milk.
- (c). Higher regard for the physical than mental training of youth.
- (d). Pure air, pure water, pure food.
- (f). Wearing loose clothing.
- (g). Natural sleep and plenty of it.
- (h). Natural labor—physical or mental, unforced.
- (i). Dwelling houses free from filth, having free access of sunlight and air.
- (j). Use of earth closets.
- (k). Prompt elimination of effete matter from the body, by the lungs, skin, bowels, and kidneys.
- (l). Frequent washing of the body.
- (m). Frequent change of all articles of clothing.
- (n). Burning of the dead.
- (o). Exercise of passions within natural prompting.
- (p). Constant occupation, physical and mental.—*Diet and Hyg. Gaz.*

A new method of making milk palatable and digestible.

DR. ROBERT T. EDER, of Boston, gives a valuable way of preparing milk where other methods have not proved useful:—A pint of milk is gently warmed. Into it is dropped, very slowly and with constant stirring, about 30 minims of the dilute hydrochloric acid of the United States Pharmacopoeia. The milk should be stirred until it cools. In this way a very fine flocculent coagulum is produced, floating in the whey, which is easily accessible to the digestive secretions, while the whole fluid has lost somewhat of the flat and cloying taste which makes it unacceptable to so many. It will be noticed that milk prepared in this way differs from the various "wheys" in the highly important particular that the casein is retained and used, instead of being separated out as a distinct product, while it avoids the bitterness of pancreatinized milk.—(*Bos. Med. and Surg. Jour.*)

The importance of menstruation in determining mental irresponsibility.

KRAFFT-EBING reaches the following conclusions on this subject:—

1. It is useful to consider the mental soundness of women during menstruation from a medico-legal point of view.
2. It is advisable where a woman is held on a criminal charge to ascertain whether the commission of the act coin-

closed with the menstrual period; and by "period" is meant not only the days when there is actual flowing, but those before and after as well.

3. It is best to advise examination of the mental condition when such coincidence is established. This is indispensable when there is a personal history of neuropathic defect of mental disturbance at the time of previous menstrual periods, or when the nature of the act reveals any striking features.

4. When the menstrual process exerts a powerful influence on the mental life of the subject, the accused should be given the benefit of extenuating circumstances in the infliction of the penalty, even although there be no proof of menstrual insanity.

5. When the offence of crime has, in a person whose mind is impaired, occurred during the menstrual period, she must be declared irresponsible, for there is every reason to think the act due to emotional impulse.

6. But individuals who by reason of menstrual insanity would benefit by acquittal on this ground should be considered as dangerous in the extreme and subjected during the times of the menses to close surveillance. It is best to confine them to any asylum for the insane where they will be comfortably cared for and often cured of this menstrual instability of mind.—*Brooklyn Med. Jour.*

Charge of manslaughter against a Midwife for spreading Puerperal Fever.

DR. DANFORD THOMAS concluded an inquiry into the circumstances attending the death of HILDA GRAY, aged twenty-four, of Peckwater-street, Kentish-town, from puerperal fever. She had been attended by a midwife, by name RAKE, who, it is alleged, had continued to attend cases after being requested by DR. J. F. SYKES, the medical officer of health of St. Pancras, to desist from doing so, his attention having been called to three cases of puerperal fever in patients under her charge, and subsequently to two more, and then to three more—eight in all. It transpired in the course of the inquiry that of these eight cases five had died and MRS. RAKE was committed for trial on a charge of manslaughter. Under these circumstances we withhold all comment on a very painful case.—*Lancet.*

THERAPEUTICS AND PHARMACOLOGY.

For Insomnia and Constipation.

IN various neuroses, where both sleeplessness and constipation are common symptoms, the following is a useful prescription:—

R Ext. Cannabis Indicæ
Ext. Belladonnæ ... ½ an gr.
Pil. Aloes c. Ferro ... iv gr.
Mt. Pil. j.

S. To be taken at bed-time, every night if required.

Treatment of Acne Rosacea.

DR. PURDON, of Belfast, advocates the following plan of treatment in acne rosacea. The dietary and any gastric derangement having been attended to, the following local plan gives good results: Bathe affected parts with a spirit of horse-radish, say, in the morning; and, at bed-time, rub in pretty firmly a pomade of sulphur with a small quantity of carbolic acid. In place of the latter, sometimes good results are obtained by substituting 10 grains of the green iodide of mercury to the ounce. All comedones should be squeezed out with an "extractor." As a "refining" agent, ichthyol is often better than sulphur.—*Dub. Jour. Med. Scienc.*

To hide the taste of Chloral.

DR. R. HOLLAND calls attention to the fact that the taste of chloral hydrate is effectively masked by kumquats. Two or three drachms of the syrup should be placed in a tumbler with about two ounces of water. If to this is added about two ounces or so of gaseous (bottled) lemonade, the mixture may be drunk at leisure, and the soporific action of the drug is in no way impaired.—*The Clinical Journal.*

Cancer of the Cervix Uteri.

R Iodoformi ... gr. xv.
Ext. opii ... gr. viij.
Ess. bergamotte ... m℥.
Ol. theobrom. ... ʒiij.

M. Sig.: To make 12 suppositories; 1 to be introduced into the vagina when necessary.—*Med. Bulletin.*

Neurasthenia.

THE following was a favorite prescription of Sir Andrew Clark's:—

R Acid Phosphate ... ʒj.
Ext. Cocœ Liquid ... ʒss.
Ext. Damian, Liquid ... ʒss.
Tr. Nucis Vom. ... m℥x.
Syrup. Zingib. ... ʒj.
Aq. ad ʒss. Ft. Doals.

S. To be taken in water at 11 A.M. and 6 P.M.

The Therapeutic value of Lactopeptine in the treatment of gastric derangements occurring in Children and Infants resident in the Tropics.

DR. WOLFENDALE writes an original article in *Medical Reprints* on the value of lactopeptine as a therapeutic agent which he considers "the most valuable of all aids to the digestive system." European children resident in the tropics soon develop gastric derangements. The child becomes languid, peevish and fretful, the stomach refuses all food, anorexia persisting. The abdomen swells, and is very tender to the touch, owing to flatulence; after a time diarrhoea set in with offensive slimy stools containing mucus and curdled milk. Or persistent constipation is present. The child wastes rapidly, the limbs shrink, and the skin becomes flabby and hangs loosely.

Two cases are cited illustrative of the marked efficacy of lactopeptine: *Case I.*—The child was resident in Tropical Africa. For the first three months brought up on breast, then fed artificially with satisfactory progress for five weeks, after that time a grave change set in. The infant became fretful and cross, appetite was lost, vomiting set in, accompanied with obstinate diarrhoea and rapid wasting. At first *hydrargyrum creta* with lactopeptine was given, whereby the diarrhoea ceased on the second day, but the vomiting though less severe, still persisted. *Bismuth* and lactopeptine were now given, 3 grs. of each every three hours. The child improved rapidly, vomiting ceased, and the milk taken was digested easily. Lactopeptine in 3 grs. doses was continued for about a fortnight; the child regaining flesh and strength each day until the original state of health was restored. *Case II.*—Boy *et. 4* years, born in England, after three months' residence in the tropics, presented all the initial symptoms of the first case, *viz.*, painful distended abdomen, wasting, complete anorexia, constipation (diarrhoea at rare intervals) and vomiting occasionally, &c. Liver and spleen were not enlarged, but the face wore a pinched, anxious appearance. The patient had among other nutritious English foods, a supply of native foods, which although nutritious, were not digestible. Treat-

meat, ketchup, and sometimes butter, and lactopeptin in a grain dose after each meal. All native foods were prohibited, and a light nutritious diet substituted at regular intervals. The child's improvement began from the fourth day, and continued steadily until all the initial symptoms subsided and he regained his usual health.

Treatment of Mental Depression in Ovarian Disease.

Dr. ROBERT FLINN finds dilute hydrobromic acid the most useful for the mental depression associated with chronic uterine or auto-ovarian disease. He prescribed it alone in several very chronic cases with marked benefit, after other drugs had failed. The dose should be R_x xx, ter in die, as less is not of much value.—B. M. J.

Caustics in Malignant Disease.

1. The value of caustics in the treatment of malignant disease depends upon the use of proper caustics in their intelligent application in suitable cases.
2. A proper caustic is one which completely destroys and removes the malignant disease.
3. Muhl caustics are inefficient and dangerous, and therefore to be avoided.
4. Bongard's or Vienna paste is the most generally useful and oclastic.
5. Proper technique in application accentuates the value of caustics.
6. The suitable cases are those which have a limited extent and are easily accessible; or, in other words, cancer of the skin, lip and external in their incipient stages.
7. The prognosis should be most excellent, cure resulting in the vast majority of cases when treatment is early and thorough.—*Kansas Med. Jour.*

Antipyrin as an Antiseptic and Hemostatic.

ROSWELL PARK, of Buffalo, has found a 4 per cent. solution of antipyrin useful as a hemostatic in checking general oozing from a bleeding surface, and also by experiment claims for its antiseptic properties which compare favorably with most of the anilin and coal tar derivatives. By experiments on animals he has shown that it can be used with safety on the peritoneum, and also now employs it in general surgery. As a styptic it has the advantage of constricting the small vessels without causing any external clot, which may break down. In cases of epistaxis he has found it useful when sprayed into the nose. In this form of a spray to the nose he has found it useful in certain cases of inflammatory occlusion, and also for ordinary headaches, coryza, etc.—B. M. J.

Uses of Stale Bread.

If properly made from wholesome and nutritious material and well preserved, there are few other foods that can be combined into more varied and palatable dishes than left-over bread. To insure the perfect preservation of the fragments, the loaf itself should receive good care. Perfectly sweet, light, well-baked bread has not the same propensity to mould as a poorer loaf, but the best of bread is likely to become musty if its surroundings are not entirely wholesome. The receptacle used for keeping the loaves should be frequently washed, scalded, and dried. Crumbs and fragments should be kept in a separate receptacle and as thoroughly cared for as is the bread. It is well in cutting bread not to slice more than will be needed, and to use one loaf before beginning on another. Bread grows stale much faster after being cut.

Whole or half slices of bread which have become too dry to be palatable may be utilized for swissbake, which may be

made by placing the bread on perforated pans or wire cooking pans and toasting in a moderate oven for a half hour or longer, until it is browned evenly throughout the entire slice. Such swissbake may be prepared in considerable quantity and kept on hand in readiness for use. It will keep any length of time if stored in a dry place. It is serviceable for toasts, is excellently used with hot milk or cream, and makes a good substitute for the old-fashioned dumplings served with fruits and meats.

Broken pieces of bread, not suitable for swissbake, make excellent *croutons*, a most palatable accompaniment for soups, gruels, hot milk, etc. To prepare the *croutons*, cut the fragments as nearly uniform in size as possible—half loaf cubes are convenient—and place them in tins in a moderate oven. Let them become crisply dry and lightly browned, but not scorched. They are preferable to crackers for use in soups, and require so little work to prepare, and are so economical withal, that one who has once tried them will be likely to keep a supply on hand. The crumbs and still smaller fragments may be utilized for thickening soups and for various dishes, recipes for some of which we give in this number:—

Scalloped Cauliflower.—Prepare the cauliflower, and stem or boil until tender. If boiled, cook in equal parts of milk and water. Separate the cauliflower into bunches of equal size, place in a pudding dish, and cover with a white or cream sauce. Then sprinkle with bread crumbs, and brown in the oven.

Scalloped Tomatoes.—Take a pint of stewed tomatoes which have been rubbed through a colander, thicken with one and one fourth cups of lightly picked crumbs of Graham or whole-wheat bread, or a sufficient quantity to make it quite thick, and salt if desired, and one half cup of sweet cream. Mix well and bake for twenty minutes.

Scalloped Turnips.—Prepare and boil whole white turnips until nearly tender; cut into thin slices, lay in an earthen pudding dish, pour over them a white sauce sufficient to cover, made by cooking a tablespoonful of flour in a pint of milk, part cream if preferred, until thickened. Season with salt, sprinkle the top lightly with grated bread crumbs, and bake in a quick oven until of a rich brown.

Savory Lentils.—Take equal quantities of stewed brown lentils that have been rubbed through a colander to remove the skins, and unfermented bread crumbs. Moisten with a little rich milk or cream, season with salt and a very little powdered sage, and brown in a moderate oven.—F. E. K. is Good Health

Quinine Blindness.

DR. CHAIRBORNE, in reporting a case of quinine amaurosis in the *New York Medical Journal*, concludes as follows:—

From the study of this subject the following conclusions may be drawn:

1. Quinine in toxic doses may produce blindness.
2. The toxic dose is distinctly indeterminate.
3. The duration of the amaurosis varies largely.
4. The field of vision remains contracted.
5. Central vision usually returns to the normal.
6. There is color blindness at first; the color perception is ultimately restored within the central field.
7. The ophthalmoscopic picture is that of wide atrophy.
8. Experiments on dogs show that there is atrophy of the entire optic tract.
9. The same experiments show that the cells of the ganglion are probably not affected.
10. Treatment is of no avail.

Correspondence.

DR. ERNEST HART ON INDIAN SANITATION AND THE MEDICAL SERVICES.

To the Editor, "INDIAN MEDICAL RECORD."

SIR,—I beg to send for publication in the *Record* the following extract from the *Times of India* reporting Mr. ERNEST HART's latest utterances, which so strangely accord with the suggested reforms put forward from time to time by the *Record*, that I feel, in simple justice to Dr. ERNEST HART they ought to be put before the local profession, though I must admit the *Record* has not gone mad in abusing Dr. HART and the Indian Medical Congress. Here is the extract verbatim from the *Times of India* :—

"MR. ERNEST HART, Editor of the *British Medical Journal* and Chairman of the Parliamentary Committee of the British Medical Association, left by Saturday's mail steamer, his departure having been hastened by illness which has prevented him from continuing his journey in the north beyond Agra, as well as from fulfilling a number of engagements in Bombay for the current week, notably a conference with the leading Mahomedans in Bombay, at which he had hoped to discuss the question of the sanitation of the Mecca pilgrimages. Before leaving on Saturday, Mr. HART found an opportunity of expressing his views on various questions connected with the organisation and work of the Medical Services in India, and with the measures taken for investigating and dealing with epidemic disease in this country. Dealing first with the organisation of the Medical Services, Mr. HART spoke of the existing system—under which the Army Medical Staff looked after the health of European troops and the Indian Medical Service, essentially a military service, was entrusted with a multiplicity of duties partly military and partly civil—as radically wrong. The officers of the Army Medical Staff were trained for a particular class of work, and, except in large cantonments, they often had so little to do that their day's work was over by eleven o'clock in the day. Here then there was obviously a great waste of professional strength. On the other hand, the Indian Medical Service were often over-burdened with a variety of duties, for most of which they had no special qualification. They had all learnt their work as army surgeons at Netley; but what preparation had they made for the diverse duties which come within the range of the Government Medical Service in India? The Indian Medical Service man seems to be expected by Government to be fit for any post that may be vacant. As Civil Surgeon it is taken for granted that he has time to look after a jail as well as the head-quarters hospital, and to be responsible for the dispensaries in his district. He is assumed to be equally fit to be in charge of a lunatic asylum, and in the capacity of Sanitary Commissioner, to supervise the sanitation of a province, though the chances are that he has had no special training for either post. No one would ever think of deliberately establishing such an anomalous state of things. But that is what is a bizarre and stereotyped system, under which men who were trained for work of one kind were put to work of quite another kind, and the consequence was that there was not only a great waste of power, but that measures of vital importance to the health of the community were either neglected or imperfectly carried out.

"Mr. HART insisted upon the importance of a greater regard being paid to the principle of specialisation of functions. The first step in this direction would be the abolition of the distinction between the medical organisation for the European and the Native armies. Let there be one military service charged with the medical care of British as well as Native regiments, and let the civil military service have an organisation of its own. We should then have in the Indian Medical Service a staff of men trained for their special duties and capable of dealing with sanitary questions as they arise. Under the present system, he said, men work their way up by seniority to a position in which they fill the dual capacity of Principal Medical Officer of the Army, and Sanitary Commissioner with the Government. What guarantee have

we that they are capable of filling the place of civil sanitary authority? Look at the administration reports which you utter year come from them? They tell the same old tale, and tell it in the same way—a tale of so many deaths from a particular disease this year contrasted with so many in the year before. This is all very well, but it is mere clerical work, and we want something more than that. We do not want to be told that there was an outbreak of typhoid or cholera at such and such a place, and that so many people died of it, and that it is probably due to pollution of the water supply or the milk supply. Yet that is all that is told. If anything like a searching inquiry is made into the condition of the food, or the water, or the milk, or the drainage, we hear nothing of it. This was what might be expected under a system which almost totally ignored bacteriological investigations. The chemical analysis of water was common enough, but this was never child's play to the bacteriological analysis of these days; yet with the exception of Mr. HANSEN of Agra, of whose work Mr. HART spoke in the highest terms, there was no one in the medical service who was carrying on investigations of this kind. Every medical officer in the service of Government ought to know how to conduct at least a preliminary bacteriological analysis of the water or milk in a locality in which typhoid or cholera broke out, and in each presidency there should be a Government bacteriologist to whom recourse could be had. He doubted whether even so simple a precaution as boiling the water and the milk on the first appearance of cholera or typhoid in a barrack was ever taken; if it was, there was no record of it in the Sanitary Commissioners' reports. Nor had the simple expedient of quarantining hospitals been resorted to as it ought to have been—"quarantining" the cooks, the cooking rooms, and the hospital attendants, and seeing that no supplies of any kind were brought into the hospital, without the source being known. A reference to the failure, in the case of the cholera outbreak at the Bombay Jamsjee Hospital, to establish any definite cause, led Mr. HART to again insist upon the importance of investigations in cases of this kind—which, he said, should be conducted by men of special attainments and well abreast of the latest scientific knowledge. As to typhoid outbreaks, one eminent authority had said that, considering the absolute control which could be exercised over the supplies, no soldier should die of typhoid in barracks without somebody being hanged for it. Yet, when these outbreaks occurred, the whole thing was treated as a mystery. Mr. HANSEN's analysis, however, of the so-called water consumed by one regiment and of the milk and the water at Lucknow and Cawnpore, showed that there was no mystery in it. Mr. HANSEN, one day, during an outbreak of cholera, came upon a lady of Joggia who were praying to Bhawanee, the goddess of cholera, to withdraw the "armies" with which she was devastating the place. He told them that he would show them the "armies," and could tell them how they might be got rid of; and, putting some polluted water under the microscope, he pointed out the cholera bacilli which were the cause of mischief. Then, to show them how the "armies" could be dispersed, he poured a few drops of permanganate of potash into the water. A good deal could be done by disseminating simple teaching on sanitation amongst the people—for instance by making known, possibly with the help of vaccination officers, that immunity can be secured by boiling all the water that is drunk as soon as cholera appears in a village. Again a civil medical service that was worthy of the name would be in close relationship with the Municipalities, and it should have power to order all necessary precautions whenever an epidemic threatened. We might have to wait a long time for any large scheme of reorganisation to be carried out. In the meantime, one simple measure ought to be adopted without delay. The "official filter" in every Indian hospital and barrack was the Macnamara—the cheapest and the worst filter in existence, for, if water containing typhoid germs were put into it, the germs remained in it, and the filter, instead of purifying the water, became a culture bed for typhoid. It should be at once replaced by the Pasteur filter, which had killed typhoid in the French army and was the best filter in existence.

I sincerely trust that you and the local profession whom you so ably and stoutly represent, will take heart from Dr. HART's attitude and look upon him as a friend, and not as a foe.

Yours &c., GEORGE LIEUT. COL., I. M. S.

BOMBAY, 21st March 1895.

MEDICAL REFORM: SOME RECENT VIEWS AND A RETROSPECT.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—It was with particular interest and pleasure that I read the remarks of MR. ERNEST HART on the subject of Indian sanitation and the Medical Service of India, which appeared in the *Times of India*; and as one who has given some thought to the subject and worked to rouse popular interest in the same, I would crave space for a few observations. It is now abundantly clear that the subject of Indian sanitation and the medical services of India is of absorbing interest not only to the profession in India, but also to the Indian people and the Government of the country. The early utterances of MR. HART at Calcutta showed traces of official coloring and provoked unfavorable comments from non-official and independent medical journals. I for one, however, awaited with much interest and no little confidence an expression of his matured opinion, after he had been in the country for sometime and had seen things with his own eyes, and drawn his own independent conclusions; for it has long been a matter of conviction with me that the existing constitution of the medical service of India can produce but one impression on the minds of those who are disposed to think for themselves, and consider the subject without bias and with information as to the present-day requirements of medical science and education. It is no small satisfaction to me to find that my utterances, both as regards the present constitution of the medical services and its working, and the necessity for a radical reconstitution of the same, should have been so much in accord with the matured views of MR. ERNEST HART. For such a clear and emphatic expression of such views the whole independent Indian profession is truly indebted to him, and to you Sir, for affording him an opportunity of publishing them to the world. Let me briefly summarise the main points of MR. HART's remarks as to the constitution of the service, and the effects of its working. MR. HART's emphatic remarks are:—It is "a bizarre and stereotyped system, with an anomalous state of things in which the I. M. S. man seems to be expected by Government to be fit for any post that may be vacant. He is assumed to be equally fit to be in charge of a lunatic asylum, and in the capacity of a sanitary commissioner to supervise the sanitation of a province, though the chances are that he has had no special training for either post." And the cause thereof is not far to seek, for says MR. HART: "The I. M. S. men are overburdened with duties for most of which they had no special qualification," and naturally so, for "they had all learnt their work as Army Surgeons in Netley; but what preparation had they made for the diverse duties which come within the range of the Government Medical Service in India?" "The existing system," MR. HART characterises, "therefore is radically wrong." As illustrations of the evils of the working of the existing system, he notices the fact that "men work their way up by seniority to a position in which they fill the dual capacity of Principal Medical Officer of the Army and Sanitary Commissioner with Government. What guarantee have we that they are capable of filling the place of chief sanitary authorities?" As a natural consequence of such a systematic development of official experts by

age gradation, he points to the official reports on medical subjects as being no better productions than "mere clerical work," for "we do not want to be told," says MR. HART, "that there was an outbreak of typhoid or cholera at such and such a place, and that so many people died of it, and that it is probably due to a pollution of the water-supply or the milk supply. Yet this is all that is told." And he might have added that under the present regime it required a severe cholera epidemic in a teaching presidency hospital to apprise the Surgeon-General, of the terrible condition of the hospital store-rooms, its filthy surroundings and inefficient and bad drainage and water-supply—conditions which seem somehow mysteriously to vanish from view and get replaced by gorgeous perfection at the annual inspection visits of the same vigilant officers. As to scientific research bearing on bacteriology, MR. HART says that with the single exception of MR. HANKIN, there was no one in the medical service who was carrying on investigations of the kind, and in this connection MR. HART urged in reference to investigations into the recent cholera outbreak at the J. J. Hospital, that it should have been conducted by men of special attainments and well abreast of the latest scientific knowledge—the very things so earnestly urged in the unsuccessful prayer of the Bombay Medical Union to the local Government. As a further and very disquieting result of the working of a system "under which (in MR. HART's words) men who were trained for the work of one kind are put to work of quite another kind." MR. HART points out that "measures of vital importance to the health of the community were either neglected or imperfectly carried out." This, I may be permitted to say, is what I have repeatedly and consistently urged, both in my memo. on the subject of the reconstruction of the civil medical service of India and its separation from the military medical service, and in my public speeches and correspondence, and which is embodied in the last Congress Resolution, viz., that "the present constitution of the higher civil medical service of India is anomalous, indefensible in principle, mischievous in practice, and unsuited to existing conditions and requirements, and opposed to the interests of the public." And this because (1) the I. M. S. enlistment is a purely military enlistment with tests and subsequent instruction suited to the requirements of a military service and a complete absence of test and instruction so much needed for the various civil departments connected with education, science and sanitation; (2) the present system means that posts are found for men and not men for posts; (3) posts are won not by merit and ability and special training, but by seniority in military standing, as when the Surgeon-General gravitates to his post by the mere weight of years, (4) because of the I. M. S. man being assumed by Government fit to play the rôle of a professor or political agent, ophthalmologist or lunacy commissioner, according as the conveniences of the service may be supposed to require; and because the very act of the donning of the Surgeon-General's hat at the prescribed age of investiture is taken by Government as carrying with it the power of infusing into the head of the individual whose turn it comes by reason of his age, to wear the hat—expert knowledge not only in one, but in all the branches of medical science.

And as to the remedy I have suggested that the military should be separated from the civil; and that inasmuch as the I. M. S. men, when on military duty, are under the Army Medical Surgeon-General, there should be an amalgamation of the military services somewhat on the plan suggested by the Crawford and Cunningham Committee; there should be one Royal Military Service, as it practically now is, under one military Surgeon-General with two branches—the British and the Indian—the latter having the care of Indian troops, and the former of the British troops. (2). The Civil Medical Service should be a distinct service with an organisation of its own, in which men are marched to their posts through the right avenues of special training and merit, wherever found, so that each department exists for itself, and leads a healthy, independent life, and is not subordinated to the convenience of any service or other interests than its own. And what does Mr. HART suggest? He insists upon the importance of the principle of specialisation of functions, and advises, as the first step the abolition of the distinction between the medical organisation for the European and Native armies. "Let there be one military medical service charged with the care of British as well as native regiments, and let the civil medical service have an organisation of its own." "We should then have in the civil medical service of the country," says Mr. HART, "a staff of men trained for the special duties and capable of dealing with sanitary questions as they arise." Only last year, when a Swedish medical professor who first would not believe that the state of things above described really existed, inquired of some people with surprise how such a state could be tolerated in the midst of British civilisation of the present day; he was startled with the remark "Oh, it is Dr. BAHADHURI who has poisoned your mind." And again, when my solitary voice in reference to the medical and scientific aspects of that memorable Tower Tragedy Case met with a powerful echo from the *British Medical Journal* and the *Lancet*—two such influential and accredited organs of British medical profession—an echo, which I may be allowed to say with some pride, practically helped my community to purge itself of the unmerited slur that was sought to be cast on it in some quarters, it was openly suggested that I had nobbled the two leading English organs. And I wonder now if some speculative and penetrating minds would not be disposed to trace some similar influence at work in the strikingly close similarity of the observations and suggestions of Mr. HART summarised in the early part of this letter, with those which I have so repeatedly expressed. Only I have not had the pleasure of meeting Mr. HART or of communicating with him, since his arrival in India. The true explanation of course is what I have already given, viz., given the right information as to what the medical service of a civilised country ought to be, and what it unfortunately happens to be here, there can be one conclusion, and only one arrived at by all unbiased and well-informed minds. My connection with the question of medical reform has been often enough misconstrued and misrepresented, and I would beg permission at this opportunity to say a few words by way of personal explanation, even at the sacrifice as it may appear to some—of modesty. My advocacy of medical reform and the

necessity of reconstruction of the civil medical service has gone through several stages. At the first stage, when I had no connection with the college, it met with affected scorn and ridicule, and a noisy chorus of whatever is, is right. We were told that everything was the "best of the best of this world," and that my cry was the cry of an expectant interloper—or of one with a chance to enter "our fields." Later, when actually in the college, my action was put down as the cry of an irregular, therefore non-military professor, and therefore not worth notice. At the same time it began to be doubted if the refrain of "whatever is, is right" was quite correct. And now has come the stage when the doubts have been reduced to certainty, and my cry of whatever is is wrong is being admitted, but of course not without a counterfeiting that I have proclaimed it so atrociously loud. And as a reason thereof, they must needs suggest the circumstance of my severance from the college. Suggestion of motives by opponents is but a *dernier resort* of baffled opposition, and a passionate inclination to throw dirt at truth. Attaching the personality of the worker is an oft-resorted dodge with some to discredit a good cause. When I had the honor to advocate the cause of the Indian mill industry before the Hygienic Congress in London, it was sought by my adversary, Mr. HOET HALLET and his party, to discredit my advocacy, by calling me a paid advocate. I was then advocating not only the cause of the mill-owners of Bombay, but also the policy of the very Government who, most unaccountably, cancelled their obligation to send me as their delegate on the score of the Bombay Surgeon-General objecting to my youth, a fault I am gradually mending. But all the same, victory came to our cause, and victory came not because of me or my advocacy, but because the cause itself was so good and true. I had only tried to be a fearless and faithful spokesman. Without a boast I may say that in my present fight thorough reform, involving a complete abandonment of the present anomalous and indefensible system, and a thorough emancipation of the Indian medical profession from the degraded condition in which it has labored so long, have been my sole aim. It is only to convenient memories that my attacks on the present system will appear recent and an outcome of my being not allowed to work at the College and Hospital even without any salary. Let me remind my opponents that, as I said at a recent gathering of my professional brethren, I was at war with the present system long before I entered college. I remained at war with the system all the time I was at the College, and I mean to do the same till thorough reform is really taken in hand and honestly carried out. The disappointment to me was the non-realisation of my very natural expectation. I had hoped that it would be understood that all the professors had but one aim, viz., the good of medical education and the advancement of science, irrespective of the service or class to which they may belong, and that I would meet with co-operation in my work of reform, as I had thought that the present race of professors walked in the footsteps of the father of the College—CHARLES MORRHEAD—himself a distinguished member of their own service, who had publicly declared that "there is probably no better mode of improving our institutions than pointing out the defects

and so fixing attention upon them, as to lead to every opportunity of correcting them being steadily and systematically taken advantage of." In attacking a system one has to give illustrations, and the more real the illustrations the more striking the awfulness of the defects, and truth, unlike fiction, bites and not barks.

In drawing upon instances for such illustrations, one must resort to personal knowledge, and it is to be deplored that such citations should have been twisted and represented as personal attacks, and have brought into being a swarm of enemies. I mind that not. For it is the pushing forward of the cause and the truth that has been the aim and not the making of friends. And if the cause has advanced so far as to wring out from the opponents a confession, and bring forth Mr. HART's authoritative and independent testimony that the present system is radically wrong and requires thorough overhauling and reconstructing on the basis of what obtains in every other civilised country, it is because the cause is as good and great as the evils of the present system are deep and multifarious, and not because of my persistent or even as some would say, acrimonious advocacy. I claim no credit for my advocacy, but I certainly do claim to have had the good fortune to be the instrument of the times in bringing to the surface the great and deep defects of the system arresting popular attention thereto and securing public co-operation for their removal. I would again appeal to the press of the country to keep busy at what really is not so much the profession as the country's cause, and I earnestly hope that success will attend the efforts that are about to be made to ventilate the subject at public meetings in the country and to memorialise the Secretary of State and the Government of India, and otherwise represent the matter by personal pleading before the bar of the British public and profession. It is a hopeful sign of the times that, as I have reason to believe, the subject has enlisted the active sympathy of many influential members of the profession and of members of the service itself resident in England; and Mr. HART, of course, is a host in himself.

One word with regard to a local matter in reference to the principle of specialisation of functions. It was the agitation on the subject of medical education and teaching and the awful results of the University examinations in physiology in a particular year for which I was not a little abused, that led to some violent changes in the college, and the issuing of the memorable reform resolution of 1889, in which it was laid down that specially qualified men were to be selected for special subjects, and that having so selected them, they were to be kept to their own subjects and not made to make a tour, as of old, of the various college professorships. And the principles were carried out at once in the instance of the chair of physiology, for which a fresh and capable man from the University of London was selected. Nay more, he had subsequently facilities to work at the subject in the London University College, Physiological Laboratory, and it was no small satisfaction that with a stroke of the pen, as it were, the primitive physiology teaching which had obtained in the Presidency College for years, was transformed into the common-sense instruction of modern times. Latterly, however, the principle and practice of men for posts and the

standard of special training were cast to the winds with a lament by way of explanation, that temporary necessities of the service may override the needs of education and science. But it is feared, as *rumour* has it, that this special and specially trained professor of physiology, to whom a further inducement of Rs. 200 a month was given, by taking on to him what used to be an appendage of the medicine professor, viz., the lectureship in hygiene, is now seen to leave his laboratory and his work for the practice of ophthalmology, and thus the physiologist is to be transformed into an ophthalmic surgeon. The pathologist, also a specially selected professor, is to be transformed into a physiologist. Thus on the leaving of the ophthalmic surgeon, it is not his class and teaching that is to be entrusted to new hands, but a general shunting and misplacing of men is to happen, so that the old and practised physiologist is to appear on the college-board as an eye-surgeon, and the old and practised pathologist as the physiologist, and somebody else as the pathologist. This is specialisation of function as understood by the Surgeon-General. It is to be hoped that Lord SANDHURST, who is fresh from a country where specialisation of function is differently understood, will set his face against this chess-board shuffling of men by the Surgeon-General in this hot country.

Yours &c., K. N. BAHADURJI, M.D., Lond.

23rd March 1895.

OFFICIAL OPINION AS TO INDIA'S MEDICAL NEEDS.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—I have just received the *Indian Medical Record* of 16th March, and write to say how cordially the great majority of the medical profession serving in India ought to agree with your proposal to bring the subject of the reform of the medical services of India, and the larger utilisation of local talent at cheaper cost before the House of Commons. In this way the overworked Indian Medical Service would be relieved of all civil duties and of all private practice. All district surgeons are apparently overworked, and as such they should be debarred from private practice, which must necessarily interfere with their official duties.

DR. HART considers the Commissioned Officers are overworked even by official duties, why not relieve them of some of their civil appointments, and give that work to the Subordinate Medical Department, who already perform the duty, and do everything except signing their names. I am sure that every one who knows the method of medical work in India must realise that it would be impossible for any medical officer to perform unaided the multifarious duties expected of him.

My name here subscribed is not intended for publication, but this letter is to let you know there are numbers of Commissioned Officers serving in India, who realise the fact that the duties which it would ordinarily take five men to do efficiently, are performed by them thoroughly in a few hours, because there are five men of the Subordinate Medical Department working under them.

Yours, &c., SCHOON MAJOR, A. M. S.

MADRAS, 22nd March 1895.

Hosp. Asst. G. Backusway Chetty relinquished charge of Nizam Hosp., Insulin, Northern Shan States, on 28th Jany., and Western charge of Gaipost Hosp., Thabaw, Northern Shan States, on 2nd Feby.

Sergeant Maj. N. Learler, A. M. S., leaves for six months, on urgent private affairs.

Mrs. H. Barlow, passed the lower standard in Hindustani.

The undermentioned officers are granted leave out of India :—
 Surg.-Major, Temp. Col. R. de la C. Corbett, D. S. O., A. M. S. for six months (p.a.); Surgn.-Maj. J. Batterby, A. M. S. for six months (p.a.); Surgn.-Maj. A. G. Rose A. M. S. for six months (p.a.); Surgn.-Capt. T. W. O'H. Hamilton, for six months (p.a.); Surgn.-Maj. S. F. Loughheed, for six months (p.a.).

Surgn.-Capt. H. S. Woolf, M.B., Med. Offr., 44th Gurkha Bde, is apptd. to charge of Manipur State, in addition to his Mil. duties, from 20th Feby.

Privilege leave for two months is granted to Hosp. Asst. Nabin Chandra Das, Bhobaganj Railway Diap., Sylhet Dist. from 6th March, and Hosp. Asst. Baikuntha Chandra Chakravarti, a superny, in Sylh t Dist, appl'd to charge of Bhobaganj Railway Diap. from 6th March during his absence.

The charge for inserting a Domestic Occurrence is Re. 1 for subscribers and Re. 2. for non-subscribers, which should be forwarded in stamps with the announcement.

FEARNSIDE.—On the 8th March, at Cannanore, the wife of Surgn.-Capt. C. F. Fearnside, I. M. S., of a daughter,

WATSON.—On the 18th March, at Calcutta, the wife of
W. B. H. Watson, Dental Surgn., of a daughter.

DR. CRESPIGNY.—On the 15th Feby. at Crowcombe, Beckenham, Eyre Champion de Crespigny, M.D., of the Bombay Medical Service, son of the late Rev. Heaton Champion de Crespigny, aged 72 years.

GILCHRIST.—On the 28th Feby. at Alverstoke, Rochester, Surgn.-Maj. W. Gilchrist, M.D., late H.E.I.C.S.—aged 88 years.

J. W. (Kimari).—Yours is a difficult position, you will find it best to make a name for yourself before you take any step to mend matters.

C. V. (Blacktown).—The transactions of the Congress are not as yet available.

J. R. S. (Nabashu).—Surgeon-Captain Wade having published his statement of the accounts of the W. M. O. Fund, it now remains for the subscribers to vote him their thanks and to communicate their views for its future management.

G. G. S. (Nature).—If you will kindly send us an abbreviated notice of the book we shall be glad to publish it.

A. N. K. M. (Tarkenton).—The certificates will be issued when ready. You are sure to be pleased with them.

2.2. (Dissapour).—Follow the advice given you, and inform us of the result.

4. N. L. (Newington) - He thought we might discuss the rules pertaining military. However, important laws regarding in private practice.

K. C. M. (Jahannad)—The response of the Government has not yet been received, but we are greatly informed that the recommendations of the Indian Medical Association are being carefully considered.

T. M. N. (Cludderghat).—You may apply to the Manager of this Journal for any medical books you need, and he will order them for you.

A Subscriber in the Station Hospital, Farnborough, who sent us on the 4th March a Government Remittance transfer receipt for Rs. 9, will greatly oblige by sending us his name, as this item was omitted by him.

We acknowledge receipt of the following with thanks:

SEWAGE FARMING IN MADRAS, AND THE
FUTURITY OF THE SYSTEM FOR INDIA.By J. NIELD COOM, M.D.C.S.
Health Officer, Madras.

How to dispose of sewage has always been a problem of paramount importance. I do not propose to discuss the laws of MANU or MOHAK, or matters of ancient history. For my present purpose sanitation may be said to have commenced in the latter half of the century. In 1837 the Royal Sewage Commissioners laid it down as an axiom that "the right way to dispose of town sewage is to apply it continuously to land." However, considerable difficulties were experienced in putting the principle into practice. The heavy soils found in most parts of England, the abundant rainfall throughout the greater part of the year, the low temperature during the winter months, when vegetable life is practically at a standstill, and the difficulty and expense of acquiring suitable lands of sufficient extent in the natural direction of the drainage, have prevented the application of the sewage to the land becoming in any sense general. In 1875 the Committee appointed by the Local Government Board to inquire into the various methods of sewage disposal reported "that land irrigation is not practicable in all cases." The object of this paper is to shew that the adverse conditions which prevented the general adoption of this method of disposing of town sewage in England are for the most part absent in India. A trial extending over a quarter of a century has been made in Madras, where the local conditions are in no way exceptionally favorable, and has proved that an almost unlimited amount of sewage can be disposed of in this way in accordance with the best hygienic principles, and further that the produce of the farms finds a ready market and realises a handsome profit on the outlay. At the same time I hope to give such practical details as will enable any one to make a more or less extended trial of the system with good prospects of success.

The idea of adopting land irrigation as the means of disposing of sewage in Madras was conceived by Mr. STANDING-LINE, the Municipal Engineer, in the year 1869. No worse site could have been found anywhere about Madras than that of the first experiment. This was in the neighbourhood of Chulay, and is now known as the D'MELLOWS Road farm. It was a dismal swamp, periodically submerged by salt water, which on evaporation deposited a saline mud. The soil was black, plastic and retentive as stiff clay. Not even a blade of grass grew there.

Operations were commenced in June 1869. The swamp was reclaimed by depositing street sweepings and was planted with guinea grass. Some crops were obtained, but subsequently difficulties were encountered. With the advent of the hot weather of 1870, evaporation increased considerably, and salt was drawn to the surface forming a saline efflorescence. If the ground was allowed to rest a few days, a large quantity of guinea grass sprang up, and some herbage, or clover, that had been planted, was not strong. A small crop of grass sprang up, which is known as cow grass

(*Cynodon Dactylon*), and is liked by cattle, though unsuitable for horses. Moreover, the surface sank irregularly, throwing out the grading of the beds and necessitating a large amount of manual labor. Later on, suspicion was made by an agricultural expert, who traced the main cause of the want of success to the sub-soil water, which was found in some parts of the farm at from four inches to two feet from the surface. The worst parts of the farm were underdrained at intervals of six feet with pipes running four feet from the surface, which was aided by the deposit of rubbish, and after this, no further difficulty was experienced. My own opinion is that the pipes in this case were of little or no use, as they were placed below the level of the sub-soil water and thus of no effect. The whole neighbourhood is low and swampy, and at the present time water is found at from eighteen inches to two feet from the surface.

The next experiment was made in 1870 at Krishnaspett, near the sea shore. Half the land taken up consisted of pure sea sand, the remainder of land which had been reclaimed with rubbish and covered with a thin stratum of sand. Here no difficulty was encountered, the soil being porous and permitting the great desideratum of sewage farming free downward percolation. Heavy crops were soon raised, amounting in 1871-72 to about 60 tons of grass per acre. Since then a number of farms have been started, the principal one being known as the Black Town farm. This is admirably situated on the Beach 2½ miles north of the town. It is so close to the shore that last year a considerable portion of it was carried away by a heavy sea. Some of the farms are in inhabited areas and are of comparatively small size. This is due to the want of any general system of drainage in the town. In my opinion the fundamental principle for any system of sewerage for Madras should be to carry all the sewage to the north and dispose of it on one large farm, which could be made by the extension of the present Black Town farm. This would be more economical, and in other ways preferable, to having a number of small farms scattered over the town.

Successful sewage-farming is to a considerable extent dependant on physical conditions. The geology and surface of Madras are thus described in a recent report by Mr. EDWARD COOMINS, C.E.:—"The surface and subsoil consists, as a rule, of deposits of white and gray sand in which occur at irregular intervals, thin beds of clay. Water is found below the surface at varying depths but generally in the low-lying parts of the districts it corresponds with the mean level of the sea. At no part of this sandy plain are there any considerable elevations of the surface, the maximum heights are from 20 to 24 feet above mean sea level, while many portions of the town are only 2 feet to 6 feet above that level. The average elevation of the surface may be taken at about 8 or 10 feet. The higher parts of the town being principally occupied by private houses with large compounds have no drainage system, provision only being made for storm water. The parts providing sewage to be disposed of are all, if anything, below the average height given, which necessitates the lifting of the sewage by pumps, either from central pumping stations or from wells on the farms."

which is a costly undertaking. At first only the water-lift of the country was used. This is known as the "pootah," and consists of a lever balanced on a strong upright and worked up and down by men stepping from one side of the fulcrum to the other. But for any kind of manual pumping to be successful, constant supervision is required, and now for the principal farms this primitive system has been superseded by the steam pump, which is in every way more satisfactory. Gwynne centrifugal pumps have been found to answer best. The Royapuram pumping station, from which the sewage of Black Town is pumped to the Black Town farms, is fitted with three of them, each 15 inches in diameter. The sewage is lifted from a well, into which three sewers empty their contents and discharged into a cast iron main, 24 inches in diameter and about a mile and a third in length, being carried the remainder of the distance of $2\frac{1}{2}$ miles in an open masonry channel. No further lifting is required after the sewage reaches the farm. Pumping at this station is carried on on an average 22½ hours daily, the amount of sewage pumped being about 3 million gallons. Night-soil is removed on the pail system, and is not supposed to enter the drains, though the urine and washings of the latrines do so. The annual rainfall varies considerably, the average being about 50 inches, which is above the general average for India. A very large proportion of it falls between the middle of October and the middle of December.

As I consider the Black Town farm to be a fair model for an Indian sewage farm, I shall describe it somewhat in detail. The sewage passes from the outfall channel through culverts with sluices into the main carriers. These are banks of earth with a channel scooped out on the top. They run in parallel lines about 432 feet apart, giving off at right angles, the secondary or distributing carriers, which are similar but somewhat smaller. The interval between the distributing carriers is 114 feet, and it is divided into two by a small bund, which runs through the beds half way between them. This may be called the central bund. The beds slope down to it from the distributing carriers. It is absent in some of the farms, but I think it is a good thing to have it, as the grass may rot at the lowest part of the slope through the water standing there longest. It percolates through the bund, and so this is avoided. There are further bunds at intervals of 6 to 8 feet running from near the distributing carriers down to the central bund. These are small and not more than 4 to 6 inches in height. They conduce to the equal distribution of the sewage over the grass. The junction of a distributing carrier with a main, is made with a stone-ware drain pipe of about 6 inches diameter. Grass grows freely over the bunds and over the carriers to the very edge of the channels, which become coated with a black sludge, which hinders the sewage from sinking in, though it allows enough percolation to keep the grass growing freely over them. Large drain tiles have been laid in some of the carriers, but they soon get displaced and serve no good purpose. The gradient of the carriers should be sufficient to ensure a fairly rapid flow without causing a scour. Where the amount of sewage to be disposed of is small, the beds should be made somewhat smaller than the measurements I have given, in order to

get even distribution. The slope from the distributing carrier to the central bund is about 1 in 32.

The system of irrigation, which has been found to answer best, is to flood the beds heavily every 3 or 4 days, though it can be done oftener without any ill effect. The method employed is to open the sluice in the outfall channel and let the sewage run into a main carrier. The drain pipes leading to the distributors to be used are left open; those which are not to be used are closed with earth and grass. If only the first part of a main carrier is required, it can be banded across at the required distance with earth. The same can be done with a distributor, which is then breached behind the barrier, and the sewage pours out and runs down the space between the distributor and the ends of the bunds that divide up the beds, and turns off between these bunds to run down the beds to the central bund. The men in charge of the farms say that they put on about 4 inches at a time, but the amount must be much larger, as a good deal of sewage sinks in before it begins to lie on the surface. This method of intermittent irrigation economises the labor on a large farm, as only a third or a quarter of it has to be attended to every day. It also gives plenty of time for air to be drawn into the interstices of the soil and provide the oxygen which is necessary both for nitrification and the formation of tissue. Most cultivators irrigate equally all the time a crop is growing, but one of great experience told me that the younger the grass the more sewage it would take. The grass should not be irrigated for 2 or 3 days before it is cut. This allows it to harden, and though it does not weigh quite so much, its quality is better and it does not wither so quickly. After the grass is cut, which is done in Madras with a sickle with a saw edge, the teeth being set the contrary way to an English saw, the ground should lie fallow for the best part of a week. The careful farmer will then take the opportunity of forking it and loosening the roots, though in some farms this is not done more than once a year. It favors the development of young roots to replace the old ones, and so preserves a healthy and vigorous growth. The beds should also be weeded. If this is done regularly, it entails very little labor, but if it is neglected, there may be some difficulty experienced. The grass is generally cut rather before it reaches maturity. The contractor reckons to cut a crop every 45 days which gives 8 crops a year. In the Municipal parks, where sewage irrigation is carried on, we do not get quite so many. The method of irrigation by blocking the channels with earth and breaching them is primitive, but it suits the native cultivator, who is very skilful with it, and it has been found to answer the purpose, so no attempt has been made to supersede it and introduce iron or wooden stoppers.

Some of the three million gallons of sewage daily pumped at the Royapuram Station is drawn off to irrigate the Robinson Park, the remainder goes to the Black Town farms. Adding together the area of the Park, the farm, and of certain private lands adjoining the farm, which are irrigated by the contractor, we get a total of 40 acres approximately. This gives a daily average of 75,000 gallons per acre. The experience of the Berlin farms is, that not more than 2,000 to 3,000 gallons of daily sewage should be allotted per acre, so that the land may

and the necessary periods of rest. At the Bedford farm in England, about 5,000 gallons per acre are pumped daily, and at the Biddington farm about 6,000 gallons, which is the largest amount I know of outside Madras. Yet the Madras contractor, who is getting 12 times as much sewage per acre as any European farm would stand, recently petitioned to have sewage irrigation stopped in the Robinson Park on the ground that he was not getting enough. This is a remarkable testimony to the porosity of the soil and the copious evaporation and transpiration that take place under the influence of the Indian sun. At times when I have visited the farm, especially after heavy rain, all the sewage was not being used, the surplus running into the sea at a point beyond the farm. The sewage which is used to irrigate the farm does not form a definite effluent, but on careful examination I have found tiny rivulets trickling down from near the bottom of the wall of sand in which the farm ends, where it drops down to join the sea shore. The amount is so small that it was a long time before I noticed it.

As regards the crops that do best, though it has been found that nearly everything will grow under sewage irrigation, later experience has confirmed the verdict of the early experimenters in Madras, that *hariali* grass (*Cynodon Dactylon*, Hind: *Dhool*) is by far the most satisfactory. It has the advantage of being indigenous; for English and French experience has shewn that the peculiar crop, whatever it may be, that suits the neighbourhood, seems to flourish under sewage. It is, moreover, a voracious feeder, and is not easily killed by excess of sewage. In the wild state in places where there is not much moisture, it creeps for the most part below the surface of the ground. Native ponies may be seen scraping the surface of the ground with their hoofs and blowing away the dust to get at it, and will graze where there is not a blade of green grass to be seen. But, when abundantly irrigated, it shoots up to a height of 2 feet or more and yields most luxuriant crops. CAPTAIN HORACE HAYES, F.R.C.V.S., says of it in his book on "Horse Management in India": "In good soil, when cultivated, it loses its creeping character and grows like English meadow grass, to which I think it is much superior." A good farm yields about 45 tons of green grass per acre, which dries down to about 15 tons of hay. This compares very favorably with the Berlin farms, which yield 25 tons of grass or 5 tons of hay. From this it would appear that the grass grown in Madras contains less water than that grown in Germany. The English sewage farms yield about the same amount of hay as the German ones. This is about double the yield from English meadow land. So, where we get one ton of hay from meadow land, we get two tons from European sewage farm and 6 tons from Madras sewage farms. This enormous difference may partly be attributed to the season of growth being continuous in India, whereas in Europe, it is limited to the summer months, and partly to the fact that a high temperature in a soil or water up to 99° Fahr., increases the activity of nitrification and consequently of vegetable growth. The hay from the Madras farms is mostly sold to the Commissariat at Rs. 45 arcon. This gives an average money yield of Rs. 0.75, or about 237 sterling, per acre, taking Rs. 18 to the pound, against £38 per acre, which is reported to be

the average price of Italian rye grass grown on the Bedford sewage farm. When the differences in the cost of land and labor in the two countries are taken into account, it is easily seen how it comes to pass that sewage farming is so much more profitable in India than in England, for we have double the produce on probably less than a quarter of the outlay. Besides, the supply of hay to the Commissariat there is a fair market for grass, and hay among horse owners in the city, especially during the hot weather when grass is scarce.

With regard to the quality of our sewage farm hay as forage I wrote to Veterinary Major W. GLANVILLE, V.D., the officer in charge of the horses of H. H. the Governor's Body Guard, and the Royal Artillery at Saint Thomas' Mount, who replied:—

"Since hay from the sewage farms has been used at the Mount, there has not been a single case of anthrax until this year, when on inquiry I found that one of the Majors was using grass-cutters' grass. This was stopped and since then we have not had a case. The same in the Body Guard. I strongly recommend hay from the sewage farms, as diseased cattle are not allowed to stray over the land, and it is by far the best forage you can get in Madras. Veterinary Colonel J. S. SHAW says that wherever dry hay has been used, anthrax has not been known, and certainly I have not seen a case. In Belgium in 1878 we had anthrax, and as soon as the grass-cutters were discharged it ceased, and has not recurred since. The same in Bangalore, except when they are compelled to use green grass, as in camps of exercise, etc. So I believe the drying-process and keeping diseased cattle off the land has a great deal to do with this immunity."

Other Veterinary Surgeons with whom I have discussed the matter have spoken equally in favor of sewage farm hay.

Hariali grass grows better from roots than from seed. The roots should be planted in rows about 6 inches apart. It spreads quickly and in about two months a light crop can be cut. If it is planted in a soil recently made by the deposit of rubbish, the irrigation should be somewhat excessive, daily will not be too often. Otherwise the heat due to fermentation may kill the grass. It is advisable to let rubbish rest for six months or more before planting it, otherwise the level of the beds may be thrown out through its sinking irregularly. After planting, if the beds keep their level, there is nothing further to be done beyond weeding and forking. Beds both of sand and of made soil, planted more than 20 years ago, are still yielding good crops, though so far as I know, they have never been ploughed up or replanted. If a bed sinks in any part a few cart loads of rubbish will restore the level. If caterpillars appear, as they occasionally do about the end of the rainy season, a little freshly-slaked lime will quickly put an end to them. Turning which, *salas* are as good as anything.

About 50 acres of land are leased to a contractor. The amount was larger, but two farms have been abolished as the sewage supplied to them was carried to the Black Town farm after the opening of No. 2 sewer, and a considerable portion of the Black Town farm was carried away last year by the sea. Eleven acres more are being acquired, to be added to the Black Town farm. The contractor also

to extend the farms, rather than to increase the effluent by underdrainage. The drains leading to the Napier Park and People's Park, have overflowed into the Cooum, by which sewage enters the river at night, when the pumps are at rest, or during heavy rains. So have the drains leading to two small peotah farms, Pudupet and Dam's Road. It is proposed to introduce storage tanks to intercept the sewage that now escapes into the river, which is inconsiderable in amount. I do not know what is referred to by disposal by soakage. In some parts of the town there is soakage, but this is due to the want of proper drains and not to sewage-farming on bad sanitary principles. Sewage-farming can only be held responsible for the disposal of sewage when it reaches its destination, and not for defects in the sewage and drainage of a town.

The price paid for land for sewage-farming in Madras has not been high; and from what I have seen of other Indian towns, I believe that cheap land suitable for the purpose would generally be procurable. In the Madras farms there are practically only two types of soil, sand and made soil. They are both porous in a high degree and to about an equal extent. To test their porosity and their purifying action on sewage, I recently performed some simple experiments. I had four filters or gauges made, each consisting of three 9-inch drain pipes joined together and cemented so as to form impervious cylinders rather more than 6 feet in length. These were placed perpendicularly on wooden stands with perforated iron plates intervening, and galvanized iron buckets placed underneath. Two of these I filled with earth from the Robinson Park and the other two with sand from the Black Town farms, first putting a few pebbles and pieces of broken pot at the bottom. On the top I put grass from the farms, partly, as I believed it would act as a strainer, partly in order to obtain any action the roots might have upon the sewage as it passed over them, and generally to reproduce as nearly as possible, the natural conditions of a farm. The soil of the Robinson Park was originally street-sweepings; it is now a rich and friable loam of a dark brown color. The soil of the Black Town farm was originally sea-sand, and as far as its physical characters are concerned, it has practically undergone no alteration, though subjected to sewage irrigation for over a decade. I put sewage in at the top and caught the effluent water in the buckets at the bottom. The time taken by the sewage to pass through varied somewhat, its first appearance being in 2 to 3 hours, when the soil was comparatively dry and $\frac{1}{2}$ to 1 hour when it was fairly moist at the time of starting the experiment. It passed through the made soil quite as quickly as through the sand, which was contrary to expectation. I began by putting 2 gallons of sewage, pint by pint, into each filter. About half of it was absorbed by the soil almost immediately, the remainder stood on the surface and percolated down much more gradually. As soon as it began to come through the first filter, I added a gallon more to each in order to get enough effluent for analysis. I sent samples of the sewage used, which was taken from the well in the Royapuram Pumping Station and of the effluents to Surgeon-Major J. L. VAN GUYZEN, M.B., F.C.S., etc. Chemical Examiner to

Government, who very kindly analysed them for me. The following are the results of his analysis:—

| Analysis Parts per 100,000. | | SUSPENDED SOLIDS. | | | | DISSOLVED SOLIDS. | | | | Chlorine. | Free ammonia. | Albuminoid ammonia. | Nitric acid. |
|-----------------------------|-------------------------------------------------------------------------------|-------------------|------------|--------|----------|-------------------|----------|----------|------------|-----------|---------------|---------------------|--------------|
| | | Organic. | Inorganic. | Total. | Organic. | Inorganic. | Total. | Organic. | Inorganic. | | | | |
| | Filtered effluent sandy soil, from Black Town Sewage Farm ... | 0.100 | 1.600 | 1.700 | 205.000 | 555.000 | 760.000 | 269.800 | 0.220 | 8.670 | 0.560 | 0.210 | |
| | Sewage from Royapuram Pumping Station ... | 12.700 | 19.700 | 32.400 | 66.000 | 299.000 | 365.000 | 170.400 | 5.200 | | | | |
| | Filtered effluent (No. 1 Filter) made soil from Robinson Park Sewage Farm ... | Trace | 0.200 | 0.200 | 117.000 | 1304.000 | 1421.000 | 138.400 | 0.024 | 16.920 | 0.056 | 0.084 | |
| | Filtered effluent (No. 2 Filter) made soil from Robinson Park Sewage Farm ... | Trace | 0.400 | 0.400 | 105.000 | 280.000 | 385.000 | 120.700 | 0.019 | 16.500 | 0.084 | 0.084 | |

The character or source of the organic matter cannot well be inferred from the above analysis in the absence of determinations of the amount of organic carbon and nitrogen present. Owing to the short space of time unavoidably allowed to the analyst, these determinations had to be omitted. The filtration performed in the experiments was necessarily imperfect. The soil in the filters was much less compact than that in the farms, where it had been rained upon and irrigated for years. If I had the means available of isolating sections of the farms without disturbing the soil and had been able to utilize a larger area in proportion to the sewage used, I believe that the effluents obtained would have been purer. The sewage put on, 2 gallons to an area of 63.6 square inches, is equivalent to 591,750 gallons an acre, which is seven times as much as the average daily amount used on the Black Town farm or more than twice the amount used at a flooding done every

three days. The sample of sewage analysed contained rather less suspended matters and free ammonia, much less combined ammonia and much more matter in solution and chlorine than are contained in English sewage of average composition. At the same time the results obtained amply demonstrate the purifying powers of the soil and are in the main in accordance with the results of English experiments. The effluent water was clear, odourless and practically colorless. The analyses shew that it contains less suspended organic impurities and much less free and albuminoid ammonia than the subsoil water in parts of Black Town of which I have analysed. It would so far pass the standards of purity adopted by the Commissioners appointed to inquire into the best means of preventing the pollution of rivers. The most noteworthy point, whether from the point of view of the sanitarian or of the agriculturist, is the retention by the soil of the suspended organic matter and ammonia in solution and the appearance in the effluent of nitrates. According to modern theories based on the experiments of M. M. SCHLESING and MENTZ and MENNIS, LAWES, GILBERT and WARRINGTON, this is due to nitrification brought about by the presence of living organisms, which specially occupy the first 18 inches of the top soil. The vital activity of these living ferments varies with the temperature, being very low near freezing point and reaching its maximum at 99° Fahr. I have not got reliable records of soil temperatures in Madras, but a few days ago (early in November) I took some temperatures of the soil on the Black Town farm in the early morning, which were over 80° Fahr., so that it is probably between 80° and 100°F generally, which is the most favorable temperature for the process, and so in the highest degree conducive to the purification of sewage. In a paper read before the Society of Arts in 1882, Mr. WARRINGTON pointed out that "a filtering medium of pure sand and limestone, treated intermittently with sewage, will after a time display considerable purifying powers, the surfaces becoming covered with oxidising organisms derived from the sewage. No such medium will, however, equal in effect a porous soil, rich in organic life." This explains what might seem strange in the results of the analysis, that the effluent from the made soil contains much less unoxidised nitrogen than that from the sand. The experiments of the rivers pollution commissioners with soils from different farms appear to shew that the cleansing power of a soil is more closely connected with physical conditions as regards porosity and fineness of division than with its chemical composition, and of two soils not differing very widely in chemical composition, namely Haulbrook and Dursley, one (the latter) was found to have twice the purifying power of the other. Judging from my experiments, it would appear that made soil, which is the finer and richer of the two, had a greater purifying power than sand, and, as the porosity is about equal, though both are admirably suited for sewage farming, where both were available made soil should be taken by preference, or sand might be covered with sweepings to a height of one or two feet to give it a more active nitrifying surface stratum. Presumably the nitrates in the effluent were in the soil when it was taken from the farm, and were the result of former nitrification, and not produced from the organic matter and ammonia in the

sewage used in the experiments. The large amount of chlorides is probably due partly to the urine contained in the sewage and partly to the proximity of the sea. The amount in the effluent from the Black Town farm soil, which was taken from a spot about 300 yards from the sea shore, was more than double that of the Robinson Park, which is more than half a mile from the sea. These experiments, imperfect as they were, and the analyses made by Dr. VAN GEYVEL convince me that the effluent percolates through our farms may safely be allowed to join the subsoil water without any fear of polluting it or in any way endangering the public health. I have already shewn good reason for believing that there is not very much of it, that the water level is not appreciably raised, and that the crops are healthy and vigorous. Hence, so far as I can see, no reason exists for underdrainage, which would, moreover, entail great difficulties and expense; for the ground is in many of the farms so level, that the effluent would not run off, so that it would have to be pumped, and there would be nowhere for it to go to, unless it were thrown on to the beds again, and so be sent round and round in a vicious circle.

Under the arrangement with the sewage farm contractor, the Municipal Commissioners undertake to pay the rent, establishment and labor. The contractor must keep in repair the sewers, drains, cisterns, channel-pipes and other things connected with the delivery of sewage in or on the farms. He must dispose of as much sewage on the land as the commissioners deliver. He must cultivate and manage the farms in the most approved manner and keep them in a clean condition, free from weeds, &c. He must allow free access to the farms to the officers and servants of the Municipality, in order that they may see in what state the farms are kept, and whether any part is in need of repair, and, if so, to give notice to the lessee, who must execute the repairs within fifteen days. The contractor has the right of constructing new wells, cisterns, &c., if he first obtains consent for the proposed work. The Commissioners agree not to stop the delivery of sewage at any one time for a longer period than five days. The contractor is allowed to cultivate or irrigate with sewage other land than Municipal land with the consent of the President, and pays to the Commissioners Rs. 250 per cawne (1 cawne = 1.322 acres) per annum for lands so cultivated. The contractor has to cultivate and irrigate any other land acquired, rented, or handed over to the Municipality, and pays the Commissioners Rs. 300 per cawne per annum for lands so cultivated. The contractor makes a deposit of a Government of India promissory note for Rs. 4,750 as security. Deductions may be made from this in the event of a breach of contract.

The contract system, which was introduced in 1888, has been found to be more profitable than working the farms departmentally. The usual objection to it is that a contractor has an eye only to profit, and will not use all the sewage on the farms for fear of injuring his crops. No trouble has been experienced from this cause in Madras, partly through the voracity of barials and partly through the well-known prodigality of the Indian cultivator in the matter of irrigation. One contractor allowed weeds and objectionable kinds of grass to gain ground, especially a kind of swamp-grass with strong interlacing roots. (Pres-

These farms have gained a field in the D'ARZELLER'S Sewage Farm and to a less extent cow-grass (Chloris barbata).

The farms are put up to public auction triennially. At the last sale in 1893 Rs. 7,250 per annum, or Rs. 21,750 for the whole period, was the highest bid. On this, if the cost of pumping on the farms be included, there was a loss on the three years as shown below :

| Income— | Rs. As. P. | Expenditure— | Rs. As. P. |
|------------------|-------------|------------------------------|-------------|
| Rent of farms .. | 21,750 0 0 | Establishment .. | 1,920 1 9 |
| | | Overtime .. | 128 10 8 |
| | | Fitters Staff .. | 721 1 8 |
| | | Labor (including pumping) .. | 35,414 5 10 |
| Loss .. | 19,239 11 6 | Rent of sewage farms .. | 2,789 8 6 |
| Total .. | 40,989 11 0 | Total .. | 40,989 11 0 |

This shows a loss of Rs. 19,239-11-6, or rather more than Rs. 6,000 a year. In 1891 the better price of Rs. 15,000 per annum, or Rs. 45,000 for the three years, was obtained. On this an actual profit of Rs. 18,807 was realised; the expenditure having been somewhat reduced. In 1894 the farms were let for Rs. 19,000 per annum or Rs. 57,000 for three years. The following is an estimate of the income and expenditure for the period :—

| Income— | Rs. As. P. | Expenditure— | Rs. As. P. |
|--------------------------|------------|---------------------------|------------|
| Rent of farms .. | 57,000 0 0 | Rent, maintenance, &c. .. | 30,630 0 0 |
| Private land .. | 14,860 0 0 | Profit .. | 46,532 0 0 |
| Added land (2½ years) .. | 5,312 0 0 | | |
| Total Rs. .. | 77,162 0 0 | Total Rs. .. | 77,162 0 0 |

The estimated profit for the period is thus seen to amount to Rs. 46,532.

The conclusions I draw from the evidence adduced are as follows :—

1. Barren land can be acquired at a moderate cost in the vicinity of most Indian towns.
2. No matter how barren the land is, if it is permeable it can be utilised for the formation of sewage farms.
3. Sewage farms in India can be laid out at small cost, a mistry with a gang of coolies being able to do the grading of the beds and make the bunds and channels.
4. Owing to growth being continuous, more crops can be raised in India than in Europe, and sewage can be more satisfactorily disposed of in very large quantities throughout the year.
5. Owing to the temperature of the soil being particularly favorable to nitrification and growth in the presence of sufficient water, the crops are very heavy.
6. Owing to the scarcity of good forage during a great part of the year, there is usually a good market for grass and hay.
7. Owing to the exclusion of diseased cattle from the farms, the grass is not liable to infection with disease germs. The hay compares favorably as a food stuff with forage from other sources.
8. Sewage-farming can be carried on in the proximity of houses without affecting the health of the residents, though it is better to locate the farms at a distance from a town as there may be some nuisance from the sewage wells and main carriers owing to the decomposition of the sewage before it reaches the farms.
9. Owing to the purity of the ground and the enormous volumes of water given off by evaporation and transpiration, underdraining is not generally necessary, though it may be in particular cases.

10. Sewage after passing through the ground is sufficiently purified to be admitted in a river, or to join the subsoil water without causing pollution.

11. The native cultivator is quite capable of laying out farms and carrying on sewage cultivation without close European supervision. He is an adept at irrigation processes, having inherited his aptitude and familiarised himself with the methods almost from the time of his birth.

12. The system is suitable to parts of India where the ground is permeable and the rainfall is not excessive. It can be carried on profitably even where the flatness of the land necessitates the use of pumps, and should yield a much higher profit where the natural slope of the land permits them to be dispensed with.

THE NECESSITY FOR AN ACT RESTRICTING THE FREE SALE OF POISONS IN BENGAL.

BY SURGEON-CADET J. F. EVANS, M.B.,

and

ASSISTANT-SERGEON CHUN LAL BONE, M.B., F.C.S.,
Chemical Examiner to the Government of Bengal.

(Continued from page 247, Vol. VIII.)

2. PROPOSITION NOW UNDER DISCUSSION.

The measures we propose may be summarised as follows :—

- (a). An Arsenic Act.
- (b). The amendment of those sections of the Bengal Municipal Act and Calcutta Municipal Consolidation Act which relate to the sale of drugs.
- (c). The amendment of those sections of the Opium Act I of 1878 which relate to the retail sale of opium.

(a.) THE ARSENIC ACT.

Import of arsenic.—As already stated, the arsenic in India is almost entirely imported into the country.

By the courtesy of Mr. C. A. SAMUELS, Officiating Collector of Customs, Calcutta, we are enabled to furnish the following statement shewing the imports and exports of arsenic at the Port of Calcutta during the last twelve years :

TABLE V.

Statement shewing the quantities of Arsenic imported and exported into and from Calcutta, in the Foreign Trade, during the official years from 1882-83 to 1893-94.

| Countries whence imported from and whither exported to | 1883-84 | 1884-85 | 1885-86 | 1886-87 | 1887-88 |
|--------------------------------------------------------|---------|---------|---------|---------|---------|
| | cwt. | cwt. | cwt. | cwt. | cwt. |
| IMPORTS. | | | | | |
| From United Kingdom | 669 | 120 | 546 | 427 | 77 |
| Germany, Hamburg | 10 | 27 | 15 | 12 | 7 |
| China Hong-kong | 30 | 108 | 448 | 18 | 43 |
| Netherlands | 2 | 2 | 2 | 2 | 2 |
| Australia Victoria | | | | | |
| Total | 727 | 277 | 989 | 461 | 139 |
| EXPORTS. | | | | | |

| Total .. | 154 | 119 | .. | 105 | 60 | 133 |

From the statement it will be seen that a very considerable quantity of *arsenic* remains in the country.

Last year the quantity was 30 tons. The fatal dose of *arsenic* for an adult is 2 grains. How then, some might say, is the poisoning by *arsenic* to be prevented, when it is such a deadly drug and when such large quantities are annually imported? But 30 tons is a small quantity compared with the 2,875 tons which constitute the average annual output of *white arsenic* at the tin works of Tavistock in Cornwall; yet fatal *arsenic* poisoning of a criminal kind is not as a consequence, frequent in the neighbourhood of Tavistock.

Uses of arsenic for trade and manufacturing purposes.—The larger portion of the *arsenic* imported into India is used in trade such as the cleansing and preparation of hides, paper, paint, wooden posts, &c., and occasionally also for agricultural purposes. The yellow variety of *arsenic* which contains from 20 to 30 per cent. of *white arsenic* is used as a pigment and largely as a depilatory.

Proposed regulations of the sale of arsenic.—Without presuming that the proposition is complete and free from defect or couched in the proper legal phraseology, the regulations of the sale of *arsenic* which we would propose take the following shape:—

Persons authorized to grant license.—That certain individuals or officials shall be entrusted by Government with the duty of granting licenses for the import, sale, purchase and possession of *arsenic* after having ascertained to their satisfaction that the applicants for such licenses are fit and proper persons to be granted the same.

General conditions of sale or purchase.—That no *arsenic* or *arsenical* preparation recognised as a poison shall be bought or sold without a license, except on the prescription of a licensed medical man, with certain exceptions relating to the practice of indigenous medicine to be hereafter specified.

Conditions regulating import of arsenic.—That persons desiring to import *arsenic* into the country must obtain a license authorizing its import, and must undertake to keep the *arsenic* in safe custody and to sell it only to persons producing a license authorizing them to purchase *arsenic*, all such sales being registered with an entry of the date, the quantity, sold and the name and address of the purchaser.

Conditions regulating wholesale or retail sale of arsenic.

—That dealers in *arsenic*, whether wholesale or retail, must obtain a license authorizing them to buy, sell and possess *arsenic*, that they must undertake to buy from and sell to licensed persons only and to carry on their business generally under the same conditions as the importers, except in so far as its sale on medical prescription is concerned.

Conditions regulating sale or purchase of arsenic for trade and manufacturing purposes.—That persons requiring *arsenic* for manufacturing and other purposes not being those of sale, retail or otherwise, must obtain a license authorizing them to buy and possess *arsenic* for such purposes and must be prepared to satisfy the licensing authorities that they are fit and proper persons to be entrusted with the possession of *arsenic*, and that they are in a position to make suitable provisions for its safe custody both during use and at other times.

Special provisions for practitioners of indigenous medicine.—That in rural districts, and where necessary in towns, the practitioners of indigenous medicine, if of good character, may be licensed to buy and possess a limited quantity of *arsenic* only in each year, and to dispense the same to their patients.

Precautions in certain cases.—That pounded *white arsenic*, except in special cases hereafter to be determined, be sold mixed with soot or indigo in the proportion of one ounce to each pound of *arsenic*.

(b.) AMENDMENT OF THOSE SECTIONS OF THE BENGAL MUNICIPAL ACT AND CALCUTTA MUNICIPAL CONSOLIDATION ACT WHICH RELATE TO THE SALE OF DRUGS.

Poisons within the meaning of the Act.—That the drugs named in the following lists to be known as Schedule A European Poisons and Schedule B Indian poisons be considered as poisons for the purposes of the Act:—

SCHEDULE A.

European Poisons.

1. Arsenic and its preparations.
2. Mercury and its preparations.
3. Antimonial preparations.
4. Strong ammonia.
5. Strong acids such as concentrated nitric, sulphuric, hydrochloric and oxalic.
6. Phosphorus.
7. Hydrocyanic acid and cyanides.
8. Opium, its alkaloids and preparations.
9. Belladonna, *datura*, *Hyocyamus*, their alkaloids and preparations.
10. *Nux vomica*, its alkaloids and preparations.
11. Aconite, its alkaloids and preparations.
12. Hydrate of chloral.
13. Chloroform.
14. Carbolic acid.
15. Cantharides and its preparations.

SCHEDULE B.

Indian Poisons.

1. White arsenic (*senko*, *semlukhar*.)
2. Red arsenic or realgar (*monchal*.)
3. Yellow arsenic or orpiment (*harital*.)
4. Corrosive sublimate (*ras-karpura*.)
5. Aconite (*mitabish*.)
6. Datura.
7. *Hyocyamus* (*klhoru-sani njwan*.)
8. *Nux vomica* bark or seed (*kuchila*.)
9. *Plumbago rosea* (*lal-chitra*.)
10. Croton seeds (*Jaipal*.)
11. Yellow oleander (*kolika*.)
12. *Cocculus Indicus* (*kakmari*.)
13. *Nerium odoratum* (*karubi*.)

Granting of license.—That in the same manner as suggested by the sale of arsenic, licenses be granted for the sale and possession of poisons.

Quantity of purchase or sale of poisons.—That except under certain conditions and in certain quantities to be specified in each case, no poison within the meaning of the act shall be bought or sold without a license except on the prescription of a licensed medical man.

Conditions of sale.—That persons engaged in the merchandise of poisons as defined by the Act must obtain a license authorizing them to carry on such business, and must undertake to conform with the provisions of the Act and not to sell poison in any quantity larger than that permitted for its retail sale other than to duly licensed individuals, except on medical prescription.

Registration of the sale.—That every sale of poisons except on medical prescription with certain exceptions relative to the practice of indigenous medicine must be duly registered in the following manner:—

- (a). Name of purchaser.
- (b). Residence of purchaser.
- (c). Object of purchase.
- (d). Authority for sale.
- (e). Quantity sold.
- (f). Date of sale.
- (g). Signature of the seller.
- (h). Signature of the purchaser.

Qualifications of persons permitted to buy and possess poisons.—That no person shall be permitted to buy and possess poisons who is unacquainted with their nature, and is not in a position to make proper arrangements for their safe custody and sale.

Proper labelling and custody of poisons.—That in the shops of individuals licensed to sell poison, the poisons are to be properly labelled with the name of the poison and the printed word POISON both in English and vernacular, and kept apart from other articles of merchandise.

Special provisions for practitioners of indigenous medicine.—That in rural districts and where necessary in towns, practitioners of indigenous medicine, if of good character, may be licensed to buy and possess and dispense to their patients limited quantities of the poisons included in Schedule B.

Registration of medical practitioners.—That all practitioners of medicine licensed to prescribe or dispense poison be registered.

Conditions regarding purchase for trade and manufacturing purposes.—That the same regulations should apply to persons requiring poisons for manufacturing and other purposes not being those of sale, as were recommended in the case of arsenic.

Special provisions for the sale or purchase of poisons for domestic purposes.—That it may be advisable to permit a limited retail sale of certain of the poisons included in the Schedules for domestic and other purposes, and that the drugs which may be sold, the quantities to be sold, and the manner of the sale be hereafter determined.

Patent and proprietary medicines.—That all patent and proprietary medicines, if found to contain poison within the meaning of the Act, come within the operation of its provisions.

(d). AMENDMENT OF THOSE CLAUSES OF THE BOARD'S EXCISE OPIMUM FORM NO. 1 WHICH RELATE TO THE RETAIL SALE OF OPIMUM.

Present limit to retail sale.—At the present time the largest quantity of opium that may be purchased from an opium vendor on one occasion by any single individual not being a licensed druggist or licensed vendor of opium, or of an intoxicating drug is five tola or two ounces.

This quantity is fixed by the Board's Excise Opium form No. 1 as the extreme limit of retail sale.

Two ounces of Indian opium is sufficient to poison from 15 to 20 individuals, provided that they are not opium-eaters.

Attention has already been drawn to the disastrous results of this system. The largeness of the quantity selected as the limit of the retail sale, was no doubt due to the wish of the authorities to interfere as little as possible with the requirements of the opium-eater, and with the use of opium as a domestic medicine.

Proposed limit to retail sale.—If the extreme limit of the retail sale of opium were fixed at $\frac{1}{4}$ th tola or about 20 grains, no interference with its use as a domestic medicine would arise, as this quantity represents from 20 to 40 ordinary medicinal doses. 20 grains is, however, for an adult less than the minimum fatal dose of Indian opium, which is much less potent (five times less at least) than Turkey opium.

Such a limit would also satisfy the requirements of a very large number of opium-eaters. The daily dose of opium eaten at the commencement of the habit is about $\frac{1}{2}$ grain, a quantity which, as is well known, undergoes gradual increase until a very much larger amount, even 100 grains daily, is ingested.

But a very considerable proportion of pronounced opium-eaters never exceed 15 to 20 grains per diem, and endeavour to subdue the craving for a larger quantity.

The question now naturally arises as to how and where, if the retail limit be fixed at 20 grains, is the opium-eater, whose daily dose exceeds this quantity, to get his daily supply?

The answer is a simple one. Either the opium-eater must be exposed to a trifling inconvenience in order to get the quantity he requires, or the danger to the general community at present existing must continue.

At the present time opium-eating is not to be regarded as a vice in any sense of the term, but only as a habit, the excessive gratification of which engenders very serious dangers to the community at large, if it requires that large and fatal doses of opium must be sold without restriction.

It is not too much to require of the opium-eater, whose daily dose has exceeded the retail limit, that he should provide himself with a certificate to that effect signed by a medical man or a respectable individual, such as the head man of his village. We would suggest that such certificates should state the daily dose required, and should be valid for one year only, and that the opium vendor on the presentation of a certificate of this kind should be authorized to sell the quantity intimated therein, provided it does not exceed five tola.

* That he do not, except to a vendor of opium or of an intoxicating drug licensed by the Collector, or to a licensed druggist, sell more than five tola of opium to any person at one time.

The proposed amendment of the Board's Excise Opium form No. 1 is accordingly as follows:—

That he do not except to a vendor of opium or of an intoxicating drug licensed by the Collector, or to a licensed druggist sell more than ½th tola of opium to any person at one time, except on the production of a certificate stating that the purchaser is an opium-eater, signed by a licensed practitioner of medicine, or a respectable resident of the locality when the quantity specified in the certificate provided it does not exceed five tolas in weight, may be sold.

All sales exceeding ½th tola to be entered in a special printed record giving in addition to the information required in para. XIV^o of form No. 1, the name and residence of the purchaser, the authority for the sale and the quantity sold.

3. DIFFICULTIES ATTENDING THE INTRODUCTION AND WORKING OF SUCH A MEASURE.

Numerous objections suggest themselves, therefore it may be as well first to enumerate those which appear most important, and then subsequently deal with them in detail.

The following are the objections which will be considered:—

(a). That no practical decrease in poisoning will result by imposing restrictions on the sale of certain poisons, while others being indigenous to the country must perforce remain easily accessible.

(b). That any change which may arise from the proposed measures will be distinctly a change for the worse, on the ground that vegetable poisons will, after the enactment of such measures be utilised to a greater extent than at present, and that such poisons are more difficult of detection than the mineral poisons now in use.

(c). That the proposed measures would necessitate an undesirable amount of interference with the domestic habits and customs of the people of the country.

(d). That they would interfere with the practice of indigenous medicine, and thereby deprive the people in many districts even of the small amount of medical aid which they can obtain at the present time.

(e). That measures of the kind proposed would interfere with trade and many useful economic practices.

Is the supposed impracticability of bringing about a decrease in poisoning correct?—Without attempting to raise the question whether the policy of temporizing with an admitted evil is correct, we would at once ask, what are the poisons which may be expected to take the place of arsenic, nuxia, opium, and other controllable poisons if these are rendered more or less inaccessible? If any such exist, they must naturally be sought among the indigenous drugs of the country, which belong for the most part to the vegetable kingdom.

That the country has many vegetable products endowed with poisonous properties, is easily learned by reference to the Pharmacographia Indica written by DICKSON, HOOPER and WARDEN. Fortunately, however, the knowledge of the poisonous properties of the majority of these substances is not yet by any means popular. They may

in consequence be considered rather as potential than actual poisons at the present time so far as the public generally are concerned.

| Date. | Quantity of Opium as submitted stores yesterday. | Quantity received this day. | Total Quantity submitted for. | Quantity sold this day. | Quantity remaining in store. |
|----------|--------------------------------------------------|-----------------------------|-------------------------------|-------------------------|------------------------------|

| | | | | | |
| | | | | | |
| | | | | | |
| | | | | | |

As judged from general information and from all the cases of poisoning which are reported, the number of indigenous vegetable poisons commonly known is very small. The following are the chief:—

| | |
|----------|--------------------|
| Opium. | Nux Vomica. |
| Datura. | Oleander. |
| Aconite. | Abrus Precatorius. |

Opium heads the list, and is responsible for more fatal cases of poisoning than any other drug; but, as already shewn, its accessibility can be controlled without imposing hardship on those who require it for a legitimate purpose.

Successful interference with the possession of *datura* is apparently hopeless. Fortunately the uncertainty of its action is tolerably well recognised. It is in consequence ill-suited to the murderer's purpose, as great risk of detection would be incurred, should the poisoned man recover. The murderer does not of necessity desire to leave the locality of the murder; the robber, on the other hand, administers *datura* to assist him in the act of theft and to cover his flight with the booty.

Datura poisoning is chiefly non-fatal.

Aconite, like *arsenic*, is an imported poison, and though its introduction into the country cannot be so easily controlled as that of arsenic, yet as the channels of introduction are well-known, a feasible plan to prevent the widespread dissemination of the drug shall be practicable. The physiological symptoms set up by the chewing of even a small fragment of *aconite* root, are a bar to its frequent use as a poison, and have frequently assisted in the discovery of the poisoner.

Nux vomica trees can hardly be said to grow wild in this part of India in the same way as *datura*. They are to be found here and there, and have generally been planted for some purpose. *Nux vomica* seeds can however be readily purchased in the bazar. One seed is sufficient to poison an individual, and one tree may produce many hundreds of seeds. As *nux vomica* trees are not numerous and do not grow wild, their cultivation, except in certain recognised places and by authorised individuals, should be prohibited.

The cases of poisoning which arise from the use of *oleander* are for the most part accidental. The plant is to be found in most gardens, and like *datura* it is a poison which cannot be removed from the reach of the people. Its poisonous properties do not seem to be very widely known, and its action is somewhat uncertain.

* That he keep a daily account entered in the following form, to be submitted at the close of each day; this account to be kept in a printed account-book to be purchased at the Collector's Office:—

The *arsenic* of *arsenic* *poison* has already been *arsenic* *poison*. The fact that it requires to be introduced *arsenic* *poison* is an efficient indication as to its employment *arsenic* *poison* very limited number of cases of cattle poisoning.

There then are the poisons which have been in use for half a century and more. The accessibility of three of them viz., *opium*, *aconite* and *new venice* can effectually be controlled. *Abrus precatorius* is seldom used, and then only as a cattle poison. *Datura* and *oleander* remain, but their use (*oleander* for homicide or suicide) is rare now, for the reasons already given, and for those reasons is not likely to become more prevalent.

It is of course, very difficult, if not almost impossible, to forestall what altered conditions may bring about; but as for many years there has been practically no apparent attempt among poisoners to strike out a new line, it may reasonably be hoped that the introduction of a restricted poison sale would for several years enforce a sensible diminution in this class of crime.

It is of some interest to note that so long ago as 1843, Dr. MOUAT, then Chemical Examiner, considered that the use of vegetable poisons was on the increase, and wrote as follows:—

"The great majority of cases of the administration of poison had hitherto been arsenic. Lately, however, the exhibition of vegetable poisons has been more resorted to from its being known to *hakims* and native druggists, that while minute traces of any mineral poison can be unerringly detected, most vegetable substances defy analysis in the present state of chemical science. Some check ought to be put to the amount of murder committed in this way, unknown and unrecorded, by legislative enactment punishing all vendors of drugs in whose possession those substances are found."

Dr. MOUAT's apprehensions have however proved groundless, for Dr. WARDEN referring to this statement was able to state in 1886—

"The above was written about 40 years ago; the fear expressed that *vegetable poisons* might supplant *arsenic* has not been verified. *Arsenic* is still the homicidal and cattle-poison of India."

It will naturally be advanced that from Dr. MOUAT's time up to the present, *arsenic* has remained easily accessible, and the necessity for discovering suitable vegetable poisons has not arisen. But even should the properties of indigenous vegetable poisons become generally known, these substances could never compete with *arsenic* in fitness for the poisoner's purpose. A comparison of the properties of *arsenic* and *vegetable poisons* as a class will at once indicate the advantages which attend the use of *arsenic*.

Properties of *arsenic* and *vegetable poisons* generally:—

| ARSENIC. | VEGETABLE POISONS. |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------|
| 1. Tasteless. | 1. Acrid, bitter or unpleasant taste. |
| 2. Certain in action. | 2. Uncertain in action due to the varying quantity of the active principle present in different specimens of the same plant. |

ARSENIC.

3. The fatal dose in a small quantity.
4. Stimulates in a remarkable manner the symptoms due to natural disease.

VEGETABLE POISONS.

3. To cause death, larger quantities are necessary of the majority of crude vegetable drugs.
4. Do not stimulate the symptoms of disease to anything like a corresponding extent.

The certainty of its action, its want of taste, the smallness of its fatal dose (2 to 3 grains), require no further comment. They alone would give to *arsenic* a place in the front rank of the poisoner's equipment in any country. But the similarity of its symptoms with those induced by disease, gives it in India a special value which is well illustrated by the following case:—

On October 28th 1894, a man was admitted into the Mayo Hospital, Calcutta, suffering from symptoms of choleraic diarrhoea. He arrived alone and stated that he had come from Moorshedabad by steamer, having purchased and eaten food in the bazar before leaving. He became ill on board the steamer. After admission, his symptoms were attributed by one of the medical officers to *arsenic poisoning*, but by three others who also examined the patient from time to time, he was considered to be suffering from choleraic diarrhoea. The man died on the 4th day after admission, and a *post-mortem* examination was held. The condition found, was one of general congestion of the alimentary canal with ulceration of the stomach and ecchymosis over the columnæ carneæ of the heart. Portions of the viscera were sent to the Chemical Examiner for analysis, which revealed the presence of *arsenic*.

It is legitimate to expect that many similar cases occurring in the district are returned without challenge as cases of cholera, if such a diversity of opinion can arise in a hospital provided with an experienced and expert medical staff.

We have reason to believe, as already stated, that acquaintance with the vegetable poisons of the country and knowledge of their properties are not by any means widely diffused even among the rural population. On the other hand, it is of course quite impossible to determine what the practical knowledge of *hakims* and native druggists may be as regards indigenous vegetable poisons.

In 1843, Dr. MOUAT suggested that *hakims* and native druggists were beginning to put their knowledge to a criminal use. Whether this holds good at the present time, and to what extent, we are quite unable to say.

In towns the practitioners of indigenous medicine are as a class, a respectable body of men. No doubt here and there black sheep are to be found among the *hakims* who are not over-scrupulous as to the methods in which they earn money.

But should the scheme proposed be put in force, the *hakims* will be dependent for a supply of drugs very important, if not essential, to him in his practice upon the evidence of good character and conduct which he can adduce. In future the *hakims* would possess a definite status. A recognised position and the discharge of responsible duties are often sufficient to deter criminal inclinations from the abatement or commission of crime.

Difficulties attending detection of vegetable poisons.—

Without implying that the detection of vegetable poisons is as certain as that of a mineral, it may yet be confidently stated, that the chemical methods for detecting vegetable poisons have considerably improved since the time of Dr. MOYAT's report already referred to. And though there is still room for further advance in this direction, much has been done and vegetable poisons can be detected by chemical analysis of viscera with a very considerable degree of certainty as compared with the results of fifty years ago. Should resort to indigenous vegetable poisons be stimulated by restrictive measures, it is probable that chemical research into the nature of these poisons, and the best methods of detecting them, would also be stimulated. Much has already been done in this direction by DYMCK, HOOPER and WARDEN.

Interference with customs and habits.—If the proposed measures be carefully reviewed, it will be seen that special cognizance has been taken of customs and habits, and the measure so drafted, that no undue interference with habits and customs can arise. In the measures to restrict the general sale of poisons, a special clause is introduced to legalise a small retail sale to unlicensed persons, the provisions of the clause to be hereafter determined.

Interference with the practice of indigenous medicine.—The practitioner of indigenous medicine will not be interfered with in his practice, but will be recognised and registered, will so far, as the general community are concerned, become a more important, a more responsible individual than heretofore.

Registration of all practitioners of medicine.—We are aware that the proposal to register the practitioners of the province has already been once made, and that it was abandoned on account of the difficulties of the task. We are now, however, approaching the matter from a different stand-point.

It is utterly impossible to conceive of any scheme for restricting the sale of poisons, unless a register is kept of those persons to be entrusted with certain privileges with regard to poisons. A licensed or registered medical practitioner is the only individual in most countries, who is allowed to prescribe, sell or possess poisons without challenge, and without having to keep a list of the quantity of poisons prescribed and sold by him in the discharge of his duties. The obligation to register his name and address is a very small matter indeed in return for such important privileges, nor need the act of registration be made unduly vexatious. All medical practitioners in the employment of Government are already registered by the Imperial and Provincial Governments, and there would be no necessity to trouble them in any way.

In Calcutta, all practitioners of medicine have to obtain a license from the Municipality, permitting them to practise, and this would simplify the registration of medical practitioners in Calcutta very greatly.

In small towns and rural districts, registration must of necessity be a very gradual process. It would follow on the exhaustion of the stock of poison in the possession of the practitioner of indigenous medicine, and the necessity of obtaining a license before it could be replenished.

A measure of this kind can only very gradually be

brought into force among a population such as that of the province of Bengal.

Numerous difficulties would no doubt be encountered in its introduction, and the full measure of benefit to be derived from its operation would only slowly be realised. But, on the other hand, without some such scheme of registration, the restriction of the sale of poisons seems impracticable.

Interference with trade.—This will practically arise only from restricting the free sale of arsenic. The value of the average annual quantity of arsenic imported into the country at the Port of Calcutta during the last ten years has been about £308 sterling, valuing the arsenic at £14 per ton.

The value of the average annual number of animals poisoned by arsenic in the province of Bengal only during the same period may be calculated as about £180 sterling.

A certain amount of annoyance must of necessity be experienced in certain trades and occupations on the introduction of a restricted sale. It is possible that certain individuals, who are now in the habit of using arsenic in their trade, may be unable to obtain it in the future. Such objections should not, however, be allowed to carry any force. The convenience of the few can hardly have weight when the interests of a population have to be considered. Those persons who are fit to be trusted with poison will be able to obtain it under conditions of restricted sale as readily as at the present time. They will however have opportunities of realising that they are responsible for the safe care of the poison, which they are permitted to buy. The value of the arsenic imported into the country at the Port of Calcutta does not indicate that any important industry would be injured by the proposed measures.

Concluding Remarks.—We have now reviewed those objections to the introduction of measures restricting the free sale of poisons which appear to us to be the most important. For many years past the introduction of such measures has been frequently recommended. It is trusted that the sketch given in our paper of the present prevalence and nature of poisoning in the province of Bengal may serve to demonstrate that the necessity still exists. Without underrating the difficulties attending the introduction and working of such a measure incident to the special conditions prevailing in India, we are confident that its introduction would be attended by great reduction in crime.

We do not pretend that the measures proposed by us are free from defect or incapable of improvement. The scheme, such as it is, is submitted for criticism. In conclusion, we have to thank Dr. SIMMON, Health Officer, Calcutta, Surgeon-Major J. B. GIBBONS, Police Surgeon, Calcutta, Dr. SASSERUSAN GHOSH, Assistant to the Health Officer, Calcutta, BABU MOHINI MOHAN CHATTERJEE, Attorney-at-Law of the Calcutta High Court and BABU SURENDRA NATH MITRA, B.A., Registrar, Bengal Secretariat, for information, and assistance in the preparation of the statistics contained in this paper.

THE CHOLERA IN INDIA

By H. H. HARRIS, M. D., F. R. S. E.

Available

Professor HARRIS, in company of Surgeon-Captain HARRIS, I. M. S., arrived in the Happy Valley District last week, and it may be interesting to the uninitiated to know how cholera inoculations are carried out in detail. The following articles constitute the requisite equipment:—

Test tubes charged with agar-agar, microscope ranging up to 1,800 power. Glass slides, glass pencil rods, spirit lamps, carbolic pixie, cedar wood oil, tin cylinders, cotton wool, and an iron kettle.

The tubes of largest size are supplied from Calcutta, charged with a quantity of agar-agar—a Japanese weed, resembling in consistency ordinary gelatine, except that it has a yellowish tinge, and maintains its solidity at a slightly higher temperature, and is not so azotic. Previous to the introduction of the comma bacillus, the agar-agar and tube are thoroughly sterilised with a view of destroying the presence of any other microbe, then a little meat extract is inserted, as the bacillus cultures prolifically in a peptone; and to obviate any trace of acidity which would retard the rapid multiplication of the microbes, the material is neutralised with just sufficient carbonate of soda and phos. of potash. The comma is put in with the aid of a sterilised glass pencil rod, (that is, a rod passed through the flame of a spirit lamp), and the tube eventually plugged an inch deep at the mouth, with cotton wool also made sterile. Fifty to a hundred or more tubes are similarly treated, according to the probable number of inoculations anticipated. The tubes are packed into a tin cylinder which is closed, and kept alongside table lamps, one on either side, the heat being equivalent to that of the body. In this position they remain for twenty-four hours, are then removed, and every sample subjected to a microscopical examination in this wise:—

A glass slide is taken, moistened across at eight points with water, as each slide indicates a sample from eight tubes. Each tube has its open end subjected to the influence of a spirit flame, the cotton removed and held by the fingers (as it must not be allowed contact with other matter), a heated pencil rod is then touched on to various parts of the agar-agar, picking off a minute particle; the mouth of the tube inflated again and plugged, is numbered and laid aside, the particle on the rod is placed on the slide and stained violet with the carbolic pixie to bring the comma out prominently; the slide is carried through the flame of the spirit lamp till all liquid portions have evaporated, and is now ready for the microscope. The examination being conducted by HARRIS with the utmost diligent care, if the sample contains anything else but the comma bacillus, that tube is rejected, and as the numbers on the slide correspond with those on the tubes, the error is easily detected. Out of ninety-four tubes examined, only one was found to contain vibrios, in two years' work, representing some forty thousand cases registered. HARRIS informs me he has had but four satisfactory tubes.

A few more prepared tubes are provided as a sort of reserve in case of future outbreaks.

The next step is preparing the material developed for transfusion to the hypodermic syringe. The same precautions against external contamination are practised. About thirty or less minims of sterilised water is added to each tube, and it is then thoroughly agitated till all the bacilli are absorbed. This mixture is drawn up into a one-and-half drachm-capacity syringe till it is full, and is ample for six or eight cases; the tubes being tilted to accumulate the syringe, any portion which might escape down its side is received into a vessel holding carbolic acid lotion and thus destroyed. Two syringes are at work: one being filled while the other is in use. The patient comes up, the needle, an inch long, is plunged deep into the muscle on the left side below the ribs, and the dose injected. The part being previously washed with carbolic acid to antiseptise the skin immediately after each injection; the needle is inserted into boiling oil for a moment. The whole process is quickly done: 550 cases occupying three hours. Every individual receives a ticket bearing his name and a number, a similar entry being made in a ledger before the operation. HARRIS retain the tickets for subsequent verification.

I omitted to mention that the algea before being put under the microscope, are covered with cedar wood oil to aid its refractory power.

The symptoms following the injection are pain at the place inoculated some five hours later on, and fever next day, when the temperature might rise to 102°. A higher temperature is viewed as favorable to the intensity of the virus.

The moment the comma's come in contact with the serum of the blood when injected, they die and are consumed by the white corpuscles, and the resulting product is the protecting element from acquiring cholera. There are no intestinal disturbances, except in about one per cent., and that in a mild way.

The dose inoculated varies with the height, size and bulk of the person. A large man receiving more than a smaller one.

The first inoculation is comparatively a mild affair, and is to be followed by another of greater intensity any time after an interval of five days, and it is prepared, I believe, preferably from a post-mortem collection of an actual case of cholera and passed through a guinea-pig.

A system so acted on is presumed to be protected from cholera, as long as a person is from small-pox who has been vaccinated, but as the inoculations have only been practised since 1892, HARRIS declines to express a definite opinion. Hence there are facts or data to record, and the discovery can merely be accepted as one based on theory and logic. A thousand cases have been inoculated in this district alone, and their progress will be carefully noted when what is termed the "cholera season" begins. The policy is very amenable to new innovations. Hence the number being contracted to the above figures. Professor HARRIS is courteous and communicative, willingly explaining every detail in connection with his work, which is being carried on at his own expense. Scientifically the whole process is very elaborate, and as an expert bacteriologist, he seems to have the courage of his convictions, and is a devoted worshipper of Koch and Pasteur. Practically, the

symptomatic manifestations appear meagre, even when compared with vaccination, as it is possible for pain and fever to be produced from traumatic causes by reason of the deep plunge of needle and rupturing of muscular fibres by inserting an innocent ten or fifteen minims of sterilised water. Owing to the intense nature of the second inoculation, the first is essential to modify its influence, whether there is any difference in protecting individuals from a chemical poison, as in snake-bite, or in micro-organisms, as in cholera and small-pox, is doubtful to decide. One thing appears moderately certain from a scientific or bacteriologist's point of view; that is, that it requires a cultivated microbe to oust his uncultured ilk, and if like is going to cure like, it brings us tolerably close to bacterial homoeopathy. Professor HAFKINE is keenly alive to the fact that his opponents and supporters are watching him carefully, and though a Russian, he is fluently acquainted with English, and keeps himself well posted in all the literature which has come to be known as "Haffkinism," by taking in every medical paper, worth reading, either in English, Russian, French or German.

On my own part, I must confess receiving an interesting lesson, and being perfectly neutral in my opinion on the subject, more perhaps from ignorance; the course of these 1,000 cases mentioned will illustrate to some extent at least, what can only be regarded at present as theory; even if the second inoculation is not performed, the first is accredited with a six months' protection.

—:—

THE THERAPEUTICS OF INDIAN MADAR (CALATROPIS GIGANTEA.)

By JOHN MORTON, M.D., L.R.C.P., & S., Edin.

Mussorie.

It would be out of place were I to give a sketch of the botanical features of Indian *madar*. They are to be found in every text-book on Indian Botany, and GRISG and OLIVER both make these significant remarks about its therapeutic uses. "The milk of the *madar* is reputed in native medicine" (OLIVER). Preparations of the plant are sometimes used in medicine (GRISG). DR. CHW in a letter to the *Indian Medical Record* says that Unani and Ayurvedic books mention it as of use in eczema, indolent and atonic ulcers and splenic fever. Every intelligent native points to *madar* as a plant possessing medicinal virtues. I therefore lay no claim to have discovered a new remedy for eczema, but I would request a recognition of its revival by my happy experience. Some notes taken at the time when I was treating my first case of eczema will find a suitable niche in this place.

An Irish lady, about 40 years of age, had been suffering from eczema extending from the axilla to the tips of her fingers of one arm for the last nine years. Every doctor in Mussorie had attempted a cure, and the list of medicines tried internally would fill a whole page of the *Indian Medical Record*. There is a family history of rheumatism, but the patient herself has had no symptoms of the disease. Anti-rheumatic drugs have therefore also had a fair chance. By accident I was asked to try a poultice of *madar* leaves. I commenced very cautiously, as the case was a very bad one; the slightest exposure to air making the inflamed

parts weep with a serious exudation, and so I applied the poultice only to the fingers. On the second day the weeping had stopped, and the parts looked healthy. It was continued for another two days, and the fingers had healed. Encouraged with this result, I applied it to the whole arm; and, miraculous to relate, this was well within a week. The surprise to patient was immense; for she, like a good Irish woman, hated Indian drugs, but has since been converted to a different opinion. It would be needless re-iteration were I to record notes of the many cases of eczema, which were cured, to speak metaphorically, in the twinkling of an eye by its use. My first case of eczema was published in the *Indian Medical Record* of 1st July 1894, and was instrumental in bringing out a discussion in the lay papers about its merits in neuralgia also. Here is an account from the *Madras Mail*:—

In your issue of the 10th instant, I see an extract from the *Indian Medical Record* of an obstinate case of eczema having been cured by the application of a poultice of the leaves of the *madar* plant (*calotropis gigantea*, known in Tamil as Yerkolam and in Kanaree as Yekada). A few years back, I suffered with a severe attack of neuralgia and tried several patent medicines such as Tonga, Tikeel, Menthol, Phenactin and several others; the doctors also could give me no relief and I had to be under the influence of narcotics to bear the excruciating pain. While thus suffering agony for several days, an old native woman recommended my using the leaves of the *madar* plant, warming them on a charcoal fire, and then applying them as a poultice on either side of my face. I would have done almost anything to obtain relief, so instead of using the leaf as recommended, I procured the milky juice of the plant, and just before going to bed with a strong opiate, I anointed my eyelids with castor oil, and then most heroically smeared my face with the juice or milk of the plant. The next morning, after a sound sleep, I got up without the slightest tinge of pain I had been suffering from for several days, but my face was like a piece of raw beef from the effects of the acrid juice. A few days after the skin peeled off, and I felt as well as ever, and since then I have not had such another attack of neuralgia. I have not the least doubt that if I applied the warmed leaves instead of the acrid juice, it would have had the same described effect, and I would have avoided the blistering. I took, however, the precaution of using the castor oil to my eyes, to prevent the juice and its fumes from injuring my eyes. This plant has not only such remarkable medicinal qualities, but produces the strongest silky fibre known, and native fishermen make fishing lines out of it, as they do not rot from repeated wettings, and are lighter and stronger than any other fibre. I have no doubt that there are many other common plants that have valuable medicinal properties not known to Europeans, but are largely used by the natives of India.

A case of leprosy ulcer healed under its influence in a short time also; but as it was published recently in the *Indian Medical Record*, most of my readers, I have no doubt, are acquainted with it. In cholera a lay friend of mine informs me that he has for years used pills made of *madar* flowers with black salt and pepper in equal quantities, gives every two hours, and it has never failed to stop rapidly all the urgent symptoms, especially diarrhoea and vomiting. If given in the first stage, one is almost certain of a cure. Where troops of remedies are

suggested many years and must with continued failure, it would not be asking too much to give *marka* a fair trial.

Enough, very much I am unable to say before your readers, any information regarding its active principle or physiological mode of action, which physiological and chemical experts can alone supply, but I have said enough for the busy practitioner, to convince him that we have here a potent drug for eczema and other diseases, and although it may be presumptuous to say so at this stage, I have an idea that I have added another drag to the pharmacopoeia of the next decade.

EARLY MARRIAGE: ITS EVIL EFFECTS ON HINDU SOCIETY.

BY HARA KALI SEN, V.L.M.S.

Raipur, Dinajpur.

Most Indian practitioners know but too well that early marriage and many of our social and religious customs are solely responsible for a good deal of the ill health that our females suffer from. We all know that to infant marriage is justly attributed the terrible physical and mental maladies that many of our race are afflicted with. But few, few indeed are those who would dare to risk the wrath of the multitudes by proclaiming the truth and cautioning the people against throwing the heavy burdens of parturition on their wives and daughters before their bodies are prepared to bear the strain.

Every man owes society a solemn duty, and that medical man or woman, who hesitates to point out to his or her patient and her parents, that the only cause of her suffering is early marriage, is a coward and an enemy to mankind. Yet many of our doctors marry their daughters at the tender age of 8 or 10 years, and deliberately condemn them to the risk of life-long widowhood to escape the horrors of which, many seek the poison cup or rush into the public brothel.

Many of my countrymen go to Europe to receive their medical education, but on coming back to India vehemently advocate child marriage and enforced widowhood and eat cow-dung to purify their souls and bodies and become pure Hindus. Can I or ought I to congratulate them on their brilliant successes at their examinations or admire them for obtaining high or responsible positions if they are cowards *socially*? Certainly not; for they cannot be heroes politically, and I do not believe that the man who is immoral privately, can be moral officially.

Physical evils.—According to Hindu usage, a boy may marry at any age but it is compulsory for a girl to marry, before puberty, as marriage after she begins to menstruate, is invalid. Eight is the most auspicious age, because that was the age of the goddess *Gouri* when she married the god *Shiva*. Among the *advocated* Hindus, the struggle for existence, their Western education, and the liberty to marry at any age act as factors to prevent girls marrying before 16; but it is not so with the illiterate masses where a bachelor or widower from 16 to 80 years of age must marry a girl 8 years old, while among the *Kalis* Brahmins one man may marry 100 girls, if he likes, and submit them long before they reach maturity to degrading and abominable marriage-rites that often culminate in murder, as exemplified by Hari Mahesh's case, in consequence of which Government raised the "age of consent" from 10

to 12 years. But how many Hari Maheshs are there that pass undetected? Hundreds or thousands probably, at least death certification and the sanctity of the *purdah* system afford abundant facilities to hide the murder or death from torture of child-wives.

We have it on the authority of the most eminent obstetricians that too early coitus, before the uterus is fully developed and properly fixed in the pelvis. Nature intended it to occupy, leads to displacement and distension of this organ with consequent menorrhagia, dysmenorrhoea, leucorrhoea, and inflammation and distortion of the uterus, vulva and vagina. Then follow the dangers of pregnancy and the dangers of too early gestation with prolonged and painful labor, instrumental delivery, metritis and uterine diseases, pelvic deformity, pelvic cellulitis and life-long ill health. The Hindu proverb, "a woman is old at 20" is verified by the fact that she is often a mother at 14 and a grandmother at 30 years of age, and that while she herself is yet a child, she annually bears a child, the constant suckling of which, combined with the tomb-like seclusion of the *zenana*, makes life a curse, and her body (in many cases), a perfect wreck.

We cannot expect weakly, very young and immature females to beget strong healthy children; and it is a well-known fact that too early sexual indulgence induces or causes phthisis, dyspepsia, diabetes, spermatorrhoea, loss of memory, imbecility, melancholia, mania and many other diseases, both mental and physical.

Moral evils.—An elevated mind and a depraved body are not compatible with each other, and as the physical and the mental phenomena are dependent one on the other, it follows that a weak body has a weak mind. This is why the Bengalee is proverbially a coward and is devoid of (or possesses very little) moral courage, strength of purpose, perseverance and resolution. This is why we have become the slaves of our passions and dare not abolish *akutashi*, early marriage, enforced widowhood, polygamy, *zenana*, and many other abominable as well as destructive institutions of caste, that degrade our sons into brute-beasts and daily kill our daughters under our very noses or induce the propagation of weakly progeny.

Social evils.—Early marriage makes boys and girls too amorous, precocious, timid and sensual, and directly leads to poverty, which latter, though it might be the friend or virtue of saints, prophets, and ascetics, is a deadly curse to society. To ruthlessly multiply the race without any pre-arrangement for the support and maintenance of our progeny is to add an additional burden to the miseries of poverty; leading to absolute destitution, especially in these hard times where famine is deliberately staring us in the face and hundreds of our university under-graduates cannot possibly obtain employment or are glad to take up situations of Rs. 20 or 30 per mensem which is totally inadequate to feed a family.

With the struggle for existence, the poverty increases and fathers with marriageable sons now demand such ruinous dowries from the parents of the daughters that are to be given in marriage, that Hindu society is really becoming a matrimonial market, where parents are purchasers and boys and girls are unsexed commodities, with the consequence that while the price of boys is daily increasing, that

to grow up depending with such rapidity that those girls who are actually sold in the marriage market, are either thrown into the gutter as slaves, or kept over to prostitution, or afterwards consigned to harlots, leprosy and other evils, as so many articles to make money by. And all this because procreation begins too early with the Hindus, and children come before the parents are in a position to support them.

With Eastern nations the male chooses his partner when he is in a position to properly maintain her; but in India the Hindu is married and often a father while he is yet a school boy, and if a son is born to him there is general rejoicing in his household; but as soon as a new daughter arrives, every tongue becomes dumb and the entire family hang their heads in sorrow.

Let but this state of things continue for a while longer, and the Hindus will surely emulate the Rajputs by immolating their infant daughters; but in such a way that while the legal lists of still-births and early deaths of female infants may enormously increase, there will probably be no prosecutions for the detection of child murder. And so long as these institutions associated with early marriage are allowed to exist, we cannot expect to remove the stumbling blocks in the path of our individual and national progress.

A MIRROR OF PRACTICE.

A PECULIAR CASE OF HAND AND FUNIS PRESENTATION: EXTRACTION OF THE CHILD: RESULT: REMARKS.

By R. K. TANDAN, M.B., C.M. (Edin.).
Medical Officer, Bhamptore.

At 1 A.M. on the 23rd September 1894, I was called by the Lady Hospital Assistant to attend to a "very difficult case of labor," as she termed it, at a village seven miles from Bhamptore. From the man who came for me I gathered—

- (1). That the woman had been in labor for the last eight days.
- (2). That two native *dhais* had been attending her all along.
- (3). That one arm and the cord were presenting.
- (4). That according to these "ladies" the child had died.
- (5). That since last evening the Lady Hospital Assistant had been in attendance and even she had been unsuccessful in relieving the woman.

I went with the man to the village, armed with suitable armamentarium, on reaching which I was at once shown into a very dirty low-thatched hut, the very stuffiness of which nearly choked me. The woman was in an æsthenic condition. The pulse was weak and thready. Her whole body was covered with a cold clammy sweat. The tongue was dry, and her breath came in gasps. On examination, I found that there was no arm in the vaginal canal: certainly the cord was there, and could be felt. I was told by the *dhai* doctor that in her attempts to get out the child the *dhai* *drum* (which was quite decomposed) had come off. I knew then there was but little hope for the woman, yet I felt something must be done to give her a last chance.

I performed external manual examination, and found that the long curved head of the foetus was not in the pelvic inlet, something high. The rest of the child was not engaged. I introduced my hand into the vagina and found that the child was rightly connected over its shoulders, so much so that I could not pass my hand far enough to reach the feet of the foetus, and I did not wish to use force. The best of rupture. Turning was therefore impossible; still quite out of question. The abdomen was presenting, and I was for a few moments in a 'fix' what to do. Acting impulsively on the impulse of the moment, I tore through the presenting abdominal wall with my finger-nail, went past the abdominal viscera, got hold of the spine with my thumb and two fingers, with a little force fractured it and bent it in two, and then with my left hand, passed in the blunt hook and engaged it in the bend I had made in the spine. I then withdrew my right hand, and with it used traction till the fractured portion got engaged in the pelvic inlet. Intermittent traction was continued, simulating the natural process of labor, and at last after half an hour's hard work, there came a sudden pain, and with that the dead foetus came away. It was a male child, and the whole body was highly decomposed. Decomposition had also begun in the abdominal viscera. The offensive smell that now permeated the whole room in which we were, can better be imagined than described. Fifteen minutes after the extraction of the child the decomposed placenta also came away. I then douched out the cavity of the uterus with corrosive lotion, put on a binder, and gave the woman ext. ergot. liq. with tinc. opii. I also prescribed quinine with a stimulant fever mixture, and left her fully an hour after the birth of the child. Next day in the afternoon, her husband came to tell me that the woman had very high fever which had been preceded by rigors, and that when he left her, she was very delirious. This was as I had expected all along, and I was therefore not surprised when I heard his report. I knew that the woman was beyond all treatment, and that she could not survive that night, yet as a *desperat* resort, I prescribed phenacetin along with a stimulant. I also directed the man to apply cold water to her head. After this I received no news about her, but I subsequently learned from a boy who came to our hospital with enlarged spleen, that the woman had died that very night.

It was a very sad case, and one that might have ended happily had it not been for the unfortunate interference of the *dhai*. In this case the woman was weak from the very beginning. The pulse was not so certain day, when a *dhai* was called in to attend. This "lady" began rubbing and scrubbing with all her might, the abdomen of her patient, just in the same way as a servant girl might the door-steps, and this application of unnecessary force must probably displaced the foetus *in utero*. Rubbing and kneading went on till the arm presented. Then this "lady" called in to assist her, another very clever "lady," who came in great hurry, and passed up her head into the uterus, perhaps tried to turn, but failed. In withdrawing her head, the cord got broken and caused the death of the child. All this being known, yet the *dhai* doctor kept on with his attempts, and forced the poor sufferer to keep on until she died.

with the intent that she was completely exhausted and killed
in the act. These facts were stated from the two
slaves by bribing and threatening them.

It is high time that the Indian Medical Association took this important matter in hand and memorialised the Government for REGISTERED "dhais."

UNEXPECTED DIFFICULTIES IN LITHOLAPAXY.

BY L. N. CHOUDHURI, L.M.S.,

Officiating Civil Surgeon, Batul, C. P.

A Hindu child, *at* 5 years, was brought to the Hoshangabad Main Dispensary, which I was in charge of, with symptoms pointing to vesical calculus. I wounded the bladder and detected stone. After an enema, the child was put under chloroform. I washed out the bladder as usual, and tried to pass a No. 8 Thompson's lithotrite, but could not succeed, the urethra being small. I then attempted a No. 4. First of all I examined the instrument, and found it closed well. I oiled, locked, and passed it in without any difficulty. I was taught by Dr. PERRY (Surgeon to the Mayo Hospital, Lahore,) to turn the handle of the instrument the *wrong way* before unlocking it each time in the bladder. This I did, and heard a fairly loud "click," which I thought to be due to the falling of the stone over the blades of the lithotrite, and did not mind it, but tried to secure the stone, which I did without any difficulty, and succeeded in breaking it. After completion of my first-crushing, and when about to withdraw the lithotrite, I noticed the instrument required extra force in the act. I evacuated the bladder, but on my second introduction of the instrument, I found the upper blade of it bent, and unable to fit the lower, and this reminded me of the "click" I heard on my first opening the instrument in the bladder and the extra force required in withdrawing it. For the time I was puzzled what to do, as I had no other smaller instrument at my disposal.

As no time was to be lost, I decided at once to have a hammer by my side at the operating table in future, to put the lithotrite right whenever necessary. I decided, after introducing, to use an extra amount of force in taking it out, as I did on the first occasion. This arrangement worked very nicely and I completed my operation satisfactorily. The child did well and was discharged after four or five days, cured. The stone was a small one, weighing only about 40 grains, and consisting of phosphates with a uric acid nucleus.

Had I not reversed the handle of the lithotrite while in the bladder, I would have certainly injured the mucosa seriously, by opening the jammed blades, with a tremendous jerk. The "click" I heard on my first opening the instrument in the bladder was due to this forcible separation of the jammed blades. The jamming being caused, no doubt, by the careless handling of the instrument by my compounder while cleaning it. Otherwise it could not possibly have been bent in crushing a 40 grain phosphatic stone.

Our able Professor, Dr. PERAZ, always insisted on our examining all instruments, to see whether they were in working order prior to commencing any operation.

A precaution which, if it had followed, would have obtained my answer. I merely examined the things, and seeing that they were for the most part in the condition (nominally) that the school instrument was in working order, with the untoward result that happened.

Had I been unable to withdraw the lithotrite from the poor child's bladder, I leave the reader to judge of the consequences!

The above case is recorded simply (1) to warn my fellow brethren to examine each and every instrument to ascertain whether they are in a workable condition or not, before commencing any operation; (2) to insist upon medical students to exert an extra amount of care in watching the details of operations, when assisting their professors, however easy or insignificant they may appear.

COMPOUND FRACTURE OF BOTH BONES OF
THE FOREARM: UNION BY SUTURE.

BY ALF. McCABE-DALLAS, L.M. DENT, L.R.C.P., &c.

Kumbhir.

A HINDU boy, aged 12 years, fell from a tree, the drop being about ten feet. He alighted on his left forearm, the arm apparently being extended at the time of contact with the ground. (Surmised from the nature of the injury).

Both bones of the left forearm were fractured at a point four inches above the wrist, the upper fragments being forced through the flesh to the extent of an inch, the ends being slightly comminuted. With every form of manipulation it seemed impossible to reduce the fracture and set the bones. Under antiseptic measures the wound was opened up fully, anteriorly, and the comminuted portion clipped off, resulting in a loss of a quarter of an inch in length. The fractured ends were brought into apposition and sutured. Three sterilised, carboliced, medium catgut sutures were used, one in front, one below, and one externally; the incised portion being similarly treated, then dusted with iodoform, dressed with boracic gauze, put up in a splint, and the patient kept in bed for a month; his arm extended and supported on a pillow. No trouble ensued, the wound healed by first intention, the sutures became organised, and the bones united rapidly. At the end of two months, the lad could use his arm fairly well, and now after four months, experiences no inconvenience whatever. I am not aware of fractured bones having been dealt with in this manner before, but as the patient was young and the bones moderately soft, the end justified the means. I doubt, however, if in an adult, where the bones are quite ossified, suturing would be admissible. The dressings were replaced every third day for the first week; a rise of temperature of a degree or so occurred, which was subdued with a little quinine and a small dose of sulphonal given for a couple of nights, as the pain prevented sleep.

Indian Medical Record

16th April, 1906.

CHOLOLITHIASIS.

As the subject of gall-stones is imperfectly known and it is impossible to say what changes in the human economy indicate an excess of essential bile constituents, Dr. J. H. HORSCHER's important paper on this subject is well worth study and from it we give the following epitome:—

Perfectly fresh human bile has a specific gravity ranging from 1,005 to 1,008, and consists chemically of bilirubin and biliverdin, mucoid nucleo-albumin, cholesterin, neutral fats, soaps, lecithin, mineral matters, traces of iron and gases in which carbonic acid predominates. The quantity of bile secreted in 24 hours varies from 10 to 80 ounces, diminishing during abstinence, and increasing immediately after meals.

Gall-stones may be of any shape, varying in size from a pin's head to as large as a nutmeg, and in color from a light yellow to deep brown or black, chemically they consist of (a) cholesterin, (b) cholesterin and bilirubin calcium, (c) calcium itself, (d) bilirubin and calcium in the proportion of one to three, (e) a combination of all the ingredients.

The causes of gall-stones may be classified thus:—(1) Those located in the common duct, and due to retention of bile and obstruction, the duct being greatly dependent for its patency on lymphatic absorption of the biliary constituents, absence of bile ingredients produces gall-stone formations, which are also absent in hydrops of the gall-bladder. (2) Those located in the gall-bladder, among which is the presence of foreign bodies, such as ascaris lumbricoides, needles, distoma hepaticum, epithelial debris and casts of intra-hepatic ducts. (3) Those located in the bile appear to depend on bile-stasis, resulting in the decomposition of the bile salts and a deposition of the cholesterine and bilirubin with a tendency to the secretion of calcium carbonate by the mucous membrane of the gall-bladder. (4) Those located in the liver tissue, of which nothing is really known.

The diagnosis of gall-stone:—(1) Previous occurrence, (2) colicky, sudden and violent paroxysmal pain, radiating from the epigastric or right hypochondriac region to the right shoulder blade, to the cardiac and lumbar regions, and intensified by pressure over the dividing line of epigastric and right hypochondriac tracts, (3) acholic faeces, (4) jaundice following the colic, (5) bile in the urine and calculi in the faeces, (6) calculi may be revealed by palpation of gall-bladder. Yet all except tenderness of the gall-bladder tumor may be absent.

The symptomatology varies with idiosyncrasies. The symptoms ordinarily show themselves after sudden physical exertion, jolting on a horse or in a carriage, or a heavy meal. Jaundice appears in the sclerotic of the eye within 24 hours after the first onset of the attack, and rapidly involves the whole of the skin, while the pulse becomes weak

and cold sweats invade the skin. With similar vomiting, tightness in chest, or shock accompanied by epistaxis, fits and syncope may manifest themselves. Calculi with the jaundice are acholic stools, and the urine, which contains the bile pigments deposits an abundance of bilanin. The colic, which ceases suddenly, showing that a calculus has either fallen back into the gall-bladder or has passed through the common duct and entered the duodenum, may be of daily occurrence, and months or even years may elapse before their recurrence. In typical cases from one gall-stone to several hundreds of calculi will be passed during colic, which immediately subsides; but more or less gastric disturbance generally remains, and shews itself by a tendency to flatus, anorexia, eructations and very often constipation, all combining to make life miserable.

Differential Diagnosis.—Renal colic may be differentiated by the pain radiating from the lumbar region down into the testes, thigh and hypogastric region, the absence of jaundice, bile in the urine and acholic faeces; the urine containing blood and pus after an attack, vesical tenesmus and tenderness over the kidneys. Concretions may also be passed. Intestinal colic differs from hepatic colic by distinctly intermittent pain beginning in the umbilical region and relieved by pressure; there may be tympanitis and contraction of abdominal muscles, but there are no signs of hepatic disturbance. Carcinoma of the pancreas has sometimes blurred the diagnosis by obstructing the common duct and giving rise to jaundice, dropy of the gall bladder and bile in the urine. It may, however, be distinguished by the rapid emaciation and cachexia, sometimes fatty but acholic stools, the presence of a fixed tumor and often nodules in the umbilical region. Though the jaundice persists, the concomitant symptoms give no history of hepatic colic. Catarrhal jaundice remains constant from 14 to 42 days, and is accompanied by pyrexia and sometimes chills, but not by hepatic colic or the passage of calculi. Appendicitis beginning suddenly with nausea, chills, high temperature, sharp pain in the epigastric region, and sometimes diarrhoea confounds the diagnosis with that of chololithiasis; but there is an absence of jaundice and of bile in the urine, the faeces are acholic and the pain becomes localized in the right iliac region with decided tenderness, local tympanitis, increased resistance, and an indurated mass makes its appearance. Echinochoecus cysts rarely originate in the region of the gall-bladder, and though they sometimes grow large enough to occlude the bile ducts and produce jaundice, there is no pain nor disturbance of gastric function, and the jaundice persists. Faecal accumulations in the transverse colon are coupled with a history of bowel-obstruction, intestinal colic and constipation; but the irregular, superficial, non-fluctuating and freely moveable mass and the treatment with purgatives will remove all doubts. Renal tumors may be differentiated by diminution of the normal quantity of urine, the presence of renal colic and lumbar pain, or there may be a sudden increase in the urine voided and a corresponding diminution in the size of the tumor. Moveable kidney may co-exist with chololithiasis or it may slip under the liver and complicate the diagnosis; but it can generally be distinguished (a) by being bean-shaped and so freely moveable that it can be replaced; (b) it does

and the respiratory movements, in spite of which it can be fixed between the hands: (c) there may be a history of renal colic, but there is certainly none of jaundice, epistaxis, hæmaturia or bile in the urine.

The complications of gall-stones.—(1). Obstruction, or dilatation of either the common or cystic ducts or of both. (2). Carcinoma of the gall-tract. (3). Cholecystitis with thickening or diverticulation or contraction, and almost entire obliteration of the gall-bladder and a deposit of connective tissue with adhesions to the surrounding organs. (4). Hydrops of the gall-bladder. (5). Rupture of the gall-bladder or bile ducts. (6). Impaction of gall-stones and suppuration in the gall-bladder. (7). Hepatic abscess. (8). Rupture of abscess into the colon, duodenum, kidneys or stomach, or through the abdominal wall.

The treatment can properly be divided into (1) *Surgical*, for which there are several methods, but the ideal operation consists in cholecysto-duodenostomy, which ensures efficient drainage of the gall-bladder and removes the tendency to fistula by establishing an anastomosis between the gall-bladder and the duodenum. (2) *Therapeutic*, which at best is only palliative. Diet and careful *regime* with laxatives may encourage the elimination of calculi by their action on the intestines and bile secretion, while remedies such as arsenic, olive oil, iron succinate, the mineral acids and the salines may relieve constipation, gastric disturbances, &c., but their action is not permanent, and they do not dissolve gall-stones.

The indications for operation are:—Hepatic abscess due to gall-stones; hepatic colic frequently occurring; gastralgia or persistent gastric disturbances with physical exhaustion, anemia or tumor in region of gall-bladder; obstruction of common duct by calculi with cholemia and gall-bladder dropy; suppurative cholecystitis, impaction of gall-stones, or hydrops of gall-bladder with obstruction of cystic duct, and dangerous complications, such as rupture of gall-tract, adhesions, carcinoma, &c.

—*—

URGENT MEDICAL REFORMS FOR INDIA.

WHILE the Indian Medical Congress of 1894 will mark an era in the history of medicine and of the medical profession in India, the practical benefits that this country will derive from the deliberations and discussions of that gathering, must to no inconsiderable degree, be attributed to the fact of its having happily secured as its crowning spirit, that grand old man of the British medical world, DR. ERNEST HART. Without the co-operation of one having the independence, thoughtfulness, conviction, and thorough acquaintance with scientific matters pertaining to our calling, the many sanitary and hygienic defects under which the country has long labored, would have continued as little unheeded as of old. The profession in India is almost altogether official. It has learned the personal benefits of adopting, in matters bearing on the acts and orders of the Government, the motto that "Silence is golden." Dr. HART, however, exposed with no uncertain voice and in no ambiguous terms, many of the ways in which the work of the profession and the sanitary needs of the country are most seriously handicapped; and when it is remembered that his utterances, so far at least as they

relate to scientific matters, are the outcome of experience of things to which he has devoted careful consideration, and with which he has dealt from youth to old age, it will, to say the least, be agreeable both to Dr. HART and to the teeming millions of India, if those utterances were not regarded as weighty and important. We are glad to find, however, that the Government is disposed to give due consideration to Dr. HART's recommendations; and that there appears to be a general awakening in the country in the cases of hygiene and preventive medicine.

We are particularly pleased to find that there is an authoritative denunciation of the system on which the medical services of the country is worked. Dr. HART plainly pronounces the existing system to be altogether wrong. It has been our object in repeated articles in the *Record* to convince the Government to this same effect—that the civil and military medical work of this country is ill distributed, unnecessarily expensive, unjustly appropriated in many particulars by certain classes and communities, that that economy compatible of course, with efficiency, was not being studied, that both our military and civil medical expenditures were unnecessarily high; in short, that the existing systems of medical provision are altogether wrong. We think it is high time that the re-organisation of the medical services of the country was closely considered on the lines broadly indicated by ourselves and by Dr. HART, (1) *viz.*, the institution of a purely civil medical organisation for civil work, and of a purely military service for European and native troops alike; (2) due consideration being given for special qualifications for work of a specific nature. We hardly think that Dr. HART will attempt to suggest the details of the work ing of his suggested reforms; nor can he be expected to be conversant with the material available in the country; and with all such local circumstances and conditions which affect the applicability or otherwise of the needed reforms. Much as Dr. HART's opinions on scientific medical problems and difficulties demand respect, it cannot for a moment be admitted that a look round the country can place one in possession of all facts of a departmental or administrative nature. As we pointed out in an editorial in our issue of 1st February 1895, Dr. HART, like most enquiring visitors to this country, has rather confused ideas of medical official and administrative details; and in many respects he has formed his opinions and drawn his conclusions from one-sided representations. While then we admit and reiterate this fact—that there is a pressing necessity for radical changes in the medical services of the country—those changes to be impartial in their operation, must be worked out and fixed, and determined by a Committee formed of representatives of the Government itself, of officials of the State medical services, and of independent or non-official members of the profession. If the help of Dr. HART as President of such a Committee can be secured, it may be safely predicted that the medical organisations of this country will be considerably better in every respect; and from Dr. HART's well-tried and well-proved interest in the medical work of this country, we may go so far as to presume that notwithstanding the many personal inconveniences entailed, he will not refuse such a Committee the help of his valuable services and exceptional experience. Something must be

done to relieve our finances of the ap-keep of that portion of our commissioned staff whose daily professional work is of the most trifling nature, and also of the maintenance of highly paid military officers for purely civil duties. We will not attempt to go into any details regarding the reforms that may be effected in the medical services of India. We leave this, as we hinted above, to a council of experienced and select advisers; but we may indicate a few of the respects in which the country appears to be preposterously lavish in its medical expenditure. It may not be altogether new ground on which we are travelling; but as it leads to very important advantages to the country, we go over the ground with unabated interest, and, if necessary, will go over it again and again, as we feel sure that repeated attacks are necessary to break down the barriers that are opposed against the advance of indigenous merit into comfortable preserves.

The proposed Indian Civil Medical Service may be recruited in much the same way as the Indian Medical Service is at present; but public health, sanitary science and hygiene, should form special subjects of the competitive examination. If any conservatism, opposing the holding of the competitive examination simultaneously in India and in England, is permitted to hold sway, one-fourth of the appointments should be reserved for Civil Assistant Surgeons of approved service and qualifications. The teaching staffs of medical schools and colleges of the country should be composed of the most carefully selected and the fittest men of the civil medical services; while the mystic power (which distinguishes no other class of mortals, but the members of the Indian Medical Service) of being transformable in the short period not of one's life time, but of his Indian service into a professor of each and every branch of an extensive and illimitable art, will cease to exert its ridiculous sway. The lavish military medical expenditure maintained in this country may be most strikingly shewn by reducing a few facts to figures. For such an illustration it will be enough to consider the figures in the most recently issued report of the Sanitary Commissioner with the Government of India, for the reports of any previous year will be found to represent virtually the same facts in the matter with which we are at present concerned.

The Native army of India has at the very least a hundred and fifty commissioned doctors to attend to its medical requirements. We are not considering the total number of officers in the Indian Medical Service, but only the number always required for duty with regiments. The strength of our native troops for the year 1893 was 127,091; and the admissions into hospital amounted to 862 *per mille* of strength. The number constantly sick was 32 *per thousand* of strength; so that in plain and equivalent terms a hundred and fifty medical officers, in receipt of salaries ranging from rupees four hundred to a thousand per mensem, are kept up, each of whom has the treatment of about 730 cases per annum, and the bulk of whose onerous professional labors consists in the treatment of a daily average of about 26 patients. Again, there are small detachments of European troops, from sixty to a hundred strong, garrisoning small posts, and provided with an officer of the Medical Staff who may be

of any rank from Surgeon-Captain to Surgeon Lieutenant-Colonel. Surely much of this must strike any one as astounding military medical extravagance, and as unjustifiably expensive medical provision. Surely, as Dr. HARTER HART said more or less in his Congress address, although in a different connection, these trifling duties may be performed by less expensive agencies. These charges may, and in all propriety should be, relegated to the Commissioned Assistant Surgeons; for it is not kind, generous, or conducive to the good of the service, that Warrant Officers, who in the winter of their departmental career attain a commission, conferred as the regulations say, "by selection for ability and merit," be subjected to the last day and hour of their service, to the galling subordination entailed in the subordinate charge of station hospitals. This question naturally presents itself—will the medical interests of the detachments or regiments which these Commissioned Assistant Surgeons may by the suggested arrangement be placed in charge of be sufficiently met? For a satisfactory answer to this question we had best consult the workings and the experiences of the past quarter of a century and over. That experience tells us that Warrant Medical Officers are commonly placed in medical charge of detachments, companies, and wings of European and Native corps, by rail and by sea, on the line of march during reliefs, in escorting sick convoys, in the field, and in outposts on active service. Warrant Medical Officers have been trusted with, and have faithfully and efficiently held medical charge of detachments, large and small, of European and Native troops; and if they have been tried and not found wanting in these important circumstances where their resources have been tested, why need we have the least misgivings as to their capacity in garrison employ, where they may generally calculate on and receive a second or third opinion in serious matters and in important cases? Again, a fair number of uncovenanted medical charges in India and Burma have always been held by Warrant Medical Officers. These charges include all the multifarious duties ordinarily demanded of District Surgeons; and for the thirty or more years that this practice has obtained, there can not be recalled a single instance in which the individual has not been equal to the charge. The foregoing, we know, is a very rough delineation of how the medical services of the country may be reconstituted, but it indicates the directions in which charge and reform are specially called for. "Time changeth all things," and there is every reason to hope that the time is not very remote, which will make the old order of medical affairs in India give place to changes similar to those which we have been advocating.

THE TREATMENT OF GANGLION.

S. DUPLAY recommends a new and simple method. He injects from 5 to 10 drops of the tincture of iodine into the ganglion. A bandage is applied partly with the object of exercising pressure and partly of fixing the adjacent articulation. The pain is but slight, and ceases on the second or third day. The cure is usually complete in five or six days. Sometimes a second injection may be necessary on the fifth or sixth day. Recurrence has been known after all the usual methods of treatment, and is one of the author's cases the ganglion had already been twice removed.

SMALL-POX AND VACCINATION IN CALCUTTA: SOME LESSONS FROM THE PRESENT EPIDEMIC.

The small-pox epidemic in Calcutta continues unabated, if anything, it rages more virulently, though the health reports do not accurately attest this fact, yet it is well known to most physicians practising in town. The registered deaths for the past few weeks have varied between 250 and 200, but 300 would be more correct. This awful mortality has swelled the death-rate to 66 per mille. Vaccination is being blamed as being non-protective in many cases. Enquiry, however, elicits the fact, that in no case where vaccination has been successful, has small-pox shewn itself. An epidemic of chicken-pox is also raging in the town, and incompetent Inspectors from the Health Department of the Municipality are reporting some such cases as small-pox. Vaccination as carried on by the Municipality, has many serious drawbacks which demand urgent attention and immediate correction. The lymph used in many instances is worthless, the calves' vesicles from which it is drawn, being dried or too far advanced to yield good lymph. Again the calves themselves are bad specimens of animals, being half starved and sickly-looking. We believe, too, that prior to being used for lymph cultivation, these animals are not subjected to a careful veterinary examination. Altogether this branch of the Health Department needs a thorough overhauling. Neglect of the very essentials of vaccination leads to more evils than one. Persons who have been subjected to inoculation as a means of protection from small-pox, are deluded into believing that they are safe from infection, inasmuch as they are given to understand that if the vaccination "takes" they are safe, and if it does not "take" they are still held to be "small-pox proof" by the influence of an earlier inoculation probably in infancy.

Owing to this false sense of security, many, who ought imperatively to be re-vaccinated because of unsuccessful inoculation, have been attacked by small-pox, and a few of these have died. The wrong therefore to the public, of using imperfect lymph, is a very serious one indeed. Another danger in the matter of vaccination is, that the public vaccinators are a class of illiterate men, who are simply taught the art of vaccinating after a fashion, but who are utterly devoid of any knowledge of the physical signs and conditions of health that should interdict vaccination, nor can they give any instruction as to the diet, general habits of life, precautions to be observed and treatment to be adopted in the course of the incubative or developmental stages of this form of inoculation. It often happens too, as frequently evidenced during the present epidemic, that these men operate badly, they are uncleanly in person and untidy in their methods, while the "hygiene of the lancet" is a matter of which they are blissfully ignorant. So that the public who trust themselves in the hands of such ignorant operators are certainly placed at a very serious disadvantage, as in many cases the complications of vaccination are often not only painful and distressing, but alarming. Altogether the neglectful and faulty methods of vaccination and the imperfect lymph used, are largely responsible for the spread of the disease,

and it is high time the municipality were made to feel that their reputation was seriously at stake in the matter of their duty in the Vaccination Department. Yet these evils could easily be avoided by placing the work of vaccination in the hands of qualified medical men, as it is done in every other civilized country in the world, except India. Such an innovation in Calcutta and other large Indian cities need be attended with no greater expense than at present, for the terms on which public vaccination is done in Great Britain by private practitioners would in no way be above what is now spent on very doubtfully trained operators of a very illiterate type indeed.

Another matter of vital importance for the sanitary welfare of Calcutta, is what we so strongly urged in our last issue, namely, the need of a special hospital to meet the constantly repeated demands of epidemic disease in this large city. We held that this was a duty and a burden that must of necessity fall upon the Municipality to provide, and we now find this plea urged in strong and unanswerable terms by another medical contemporary. Let us hope the public press will voice this crying need of Calcutta till the Municipality recognises it, and what is of greater importance, meets it by suitable action.

COMMENTS AND NEWS.

INDIAN HEMP-DRUGS COMMISSION.

AFTER a patient and very careful enquiry into this subject, the Commission find that there was infinitely more sensational description than truth of the excessive use of hemp-drugs, bringing the consumer to poverty and inducing him to crime by creating physical, mental or moral disengagement, and as these drugs afford a harmless pleasure and in some acts as a beneficial stimulant to over a million people in India, who could not well afford any other stimulant, it would amount to oppression to recommend "prohibition," which therefore they put aside and take up the question of control and taxation being carried out on equal footing all over India. Except as concerns the supply (which they would prohibit) from Native states which do not follow the policy of British India, they would remove the import, export and transport duties on hemp-drugs and fixing the maximum of private possession at 5 tolas for *gunja* and *charas* and 20 tolas for *dhany*; they would refuse "sale licenses" to females, and prohibit the sale of the drugs to children or insane persons.

With a view to prevent smuggling, to exercise perfect control by the Government over the supply, and to bring the systems in different parts of India in harmony with each other, the Commission make the following suggestions which the Governor-General in Council approves generally of:—
(1) Free cultivation and manufacture of hemp-drugs be prohibited, and the bonded warehouse system introduced, where a duty of not less than Rs. 50, per maund be levied on *charas* when taken out of bond by the vendors; and where possible *dhany* and *gunja* should pay revenue duty.
(2) Separate licenses by highest-bidder auction should be granted for the sale of the different kinds of drugs, and retail and wholesale licenses not to be granted to the same person.
(3) That when new shops are proposed, municipal bodies, rural notables, tribal headmen or zamindars should first be consulted as to their locality and the necessity of opening them.
(4) The Native states should be asked to co-operate with the Indian Government.
(5) These restrictions to extend to Burma also.

WHEN SHOULD WE OPERATE ON UTERINE FIBROIDS?

WHETHER they be the size of a walnut or as large as a fetal head, DR. WINGLOW ANDERSON maintains that the removal of uterine fibromata is imperative, whenever they cause any of the following symptoms:—(1) Repeated miscarriages and tubal or extra-uterine pregnancies; (2) where the tumor is so large as to interfere with the patient's movements or usefulness, or to seriously complicate child-birth; (3) severe menorrhagia or metrorrhagia; (4) repeated attacks of pelvic peritonitis; (5) severe pain on pressure; (6) malignant or necrotic derangement; (7) cystitis, dysuria, hydronephrosis, severe hemorrhoids, varicose veins of lower extremities, and uncontrollable reflex nervous and nutritive disturbances. He is all the more in favor of early operation, as in many instances delays are dangerous; the risks and difficulties of operation increasing with the size of the tumor, the patient's age, the reduction of her vitality, nutritive disturbances, &c., and while waiting for *vis medicatrix naturæ*, calcareous, carcinomatous, cystic, necrotic, pus-forming and sarcomatous degeneration may occur. Very many observers acquiesce in these conclusions. MARTIN records several cases where fibromata have retrogressed into carcinomatous and sarcomatous degeneration. EBENDORFER claims that the mucosa of a fibroid uterus may become carcinomatous, and LEOPOLD, who noted the same thing, also maintains that fibromata may become fibrosarcomata, a metamorphosis that EMMETT, KLEBS and SIR JAMES Y. SIMPSON have also called attention to. Casually referring to the *thirteen* systems of operation now in vogue; he advocates in favor of making the operation as *rapid* and bloodless as possible, and leaving *very little* cervical tissue (if any be left) in the pelvis, and shewing that the majority of these operations are mere modifications of each other, reclassifies them and gives the following results in which the numerators represent the mortality, and the denominators the number of operations:—Enucleation by vagina, $\frac{1}{11}$; vaginal total extirpation, $\frac{1}{11}$; oophorectomy, $\frac{1}{11}$; myomectomy, or abdominal hysterectomy with intra-peritoneal treatment of stump, $\frac{1}{11}$; and with extra-peritoneal treatment, $\frac{1}{11}$.

KALA AZAR IN ASSAM.

IT was not till near the close of 1892 that *kala azar* was recognised as a distinct disease, and the deaths therefrom separated from those caused by the ordinary types of malarial fever. The figures for 1894 are not yet forthcoming, but as those for 1893 shewed 5,407 deaths from *kala azar* alone, and 9,532 from malarious fevers, including *kala azar*, DR. WARBURTON, the Sanitary Commissioner of Assam, made an investigation from which nothing conclusive was derived, beyond the fact that change of climate, or a sea voyage was without the remedial effect usual in the ordinary types of malarial fever, and he fell into the error of saying that Europeans were exempt, and that efficient sanitary measures were a check, if not a preventive, of the disease. Later on, DR. DODDS PRICE, whose views were supported by DRs. S. O. BISHOP, R. BROOKER, C. J. HANCOCK, J. HEWAN, J. C. LAVERTINE, R. R. SCOVELL, W. H. SHAND, and E. W. WITHAM, stated that though there was a possible probability of malarial poisoning, *kala azar* was no ordinary form of malaria, nor does it respond in the *slightest degree*, to anti-malarial treatment. That appearing as a severe continued fever of 14 to 25 days' duration, and frequent recurrence with a high temperature, enlargement of both spleen and liver, oedema of face and extremities, and sometimes complicated with diarrhoea, dropsy or dysentery, it differs in every particular

from ancylostomiasis, with which it has been confounded, and though prevalent to a great extent in certain districts, where it spares neither young, nor old, strong nor weak, white nor colored, it is entirely unknown in Upper Assam, above Nowgong, but it is certainly and steadily advancing up the valley, Anæmia usually absent in the beginning, becomes more or less marked, as the case progresses, and extreme emaciation often accompanies its termination; but notwithstanding the inability of the patient to digest his food, the appetite remains good to the very last; and it is curious that while the thermometer registers a body-heat ranging from 101 to 102.4°F, the patient often thinks that he is free from fever.

SOME METHODS OF STUDYING CASES.

As increased success means increase of practice, and as therapeutics is to the physician and antiseptics to the surgeon, what logistres and strategy are to the general commanding an army, so DR. GUY C. M. GODFREY enjoins the necessity for a well-balanced mental and physical training to sharpen the diagnostic powers of the doctor, and help him to appreciate that the *careful* study of a case has a two-fold value—an *immediate* one, wherein the patient benefits and the physician gets the culos of being clever, attentive and successful, and a *remote* yet infinite value accruing to the physician himself and aiding him in the treatment of future cases. A knowledge of human nature and an insight into character are essential aids to gauge the mental and physical energy of the patient by giving an idea of his will power, intelligence and self-confidence, and the probability of his following directions regarding rest, medicine, diet or habits.

The *inductive* system of reasoning by assuming that correctness of cause shews correctness of result, and the *deductive* system successively establishes the causes from the results obtained. Therefore from the history of the case before him, the physician obtains certain features enabling him to reason from cause

| To | Symptoms. | Treatment. | Morbid Anatomy. |
|--------------------------------------|----------------------------------|-----------------------------|-----------------|
| To Cause, Treatment, Morbid Anatomy. | Cause, Symptoms, Morbid Anatomy. | Cause, Treatment, Symptoms. | |

and from any one of these back to the other, thus producing proofs that are not merely added proofs; but proofs increasing in regular arithmetical progression. True, all these are not always together needed in every case, nor can they always be reasoned out at the bedside of the patient at one or two sittings, nevertheless they are strong points that should never be lost sight of, and should occupy the mind of the thoughtful practitioner in his leisure moments.

REPORT OF THE BURMAH CHEMICAL EXAMINER.

DURING 1894, the Chemical Examiner for Burma made 1,059 investigations, being:—Customs and excise 148, medico-legal 210, miscellaneous 75, oils 108 and waters 458. Among these were 187 microscopical examinations of stains for blood or semen, and one to see whether two pieces of hair belonged to the same person; 70 cases of suspected human poisoning with 25 detections, comprising arsenic 15, datura 3, other poisons 3, and only one of opium, and two cases for cattle poisoning with one detection only, in which white arsenic was found in the food, but not in the contents of the stomach. With the exception of the opium poisoning, all the other cases shew an increase over previous years. And the waters examined in 1894 exceeded those analysed in 1893 by just 99 samples; but the work is likely to decrease as the customs officials have taken to do their own proof-strength testings, and the water of the jails is to be examined twice a year only instead of four times as has hitherto been done.

THE STRAWBERRY AND SOME OF ITS USES.

Like most other berries and small fruits, strawberries are far more wholesome when eaten alone; but if cream is insisted on, it is better to let each person add it to his dish just before eating the berries, otherwise the cream quickly curdles, rendering the dish unsightly and spoiling the flavor of the fruit. *Good Health* gives us three nice recipes:—

Strawberry Minibe Pudding.—Thoroughly scald a quart of strawberries in a pint of water, sweeten to taste, skim out the fruit, cook the boiling juice with a scant cup of granulated wheat flour (i.e., *Bolong*, or *sojree*) for 15 to 20 minutes, pour over the fruit, and serve cold with cream sauce.

Sago Fruit-Pudding.—Soak a small cup of sago (or tapioca) for an hour or two in just sufficient water to cover it. Drain off the superfluous water. Transfer the sago with $\frac{3}{4}$ of a cup of sugar into a quart of boiling water, and boil till it is perfectly transparent, then pour into it a pint of nicely hulled strawberries (or raspberries or cherries, &c.) stir gently. Turn into moulds to cool and serve with cream.

Strawberry Manioca Mould.—Into half a pint of boiling water place four tablespoonfuls of manioca, and cook till it is transparent and thickened. Remove from the fire, add a tablespoonful of lime juice and a cup of sugar. Place in alternate layers with red strawberries, in a pudding dish. Let it cool until well moulded, and serve in slices with cream flavored with rose.

AMENDMENT OF THE MEDICAL ACTS.

It is apparent that the Medical Acts and the Dentists Act of 1878 were insufficient to meet all exigencies, for under the short title of "The Medical (Unqualified Practitioner's) Act 1893," a draft bill of some 8 clauses is to be put before the Parliamentary Bills Committee for consideration, digestion, and forwarding to the proper authorities for passing and legalising. It provides a penalty of £20 on a summary conviction and a default judgment of 30 days, for using, signing or exhibiting or taking any medical title that one is not duly qualified to use, &c., and imprisonment for one year with or without hard labor, to any such person who is convicted on indictment for causing grievous bodily harm to any one by operation or the administration of some treatment, without being duly qualified to do so. The exceptions that this bill cannot touch are those registered under the old Act, the possessors of a diploma from Great Britain or its affiliated colonial medical colleges, those whose names have been struck off the register as having ceased to practise, and those who possess a diploma granted by any British colony or some other country for practising medicine, &c., shall also be exempted for signing their abbreviated titles and coming to England, provided that they do not carry on or intend to carry on the practice of medicine, surgery &c. in Britain, or have come to the United Kingdom for some special operation.

INDIAN MEDICAL MATTERS IN PARLIAMENT.

AMONG the objects sought for by an early representation to Parliament of India's grievances and India's needs are:—(1) To put a stop to military surgeons going into civil duty, (2) to cause all military surgeons, now in civil work, to return to military duty, (3) to throw the "expert" or specialist's posts and teaching appointments open to competition here and in England, (4) to instal the *Uncoventant* as the nucleus of the *Indian Civil Medical Service*, and to fill up all civil vacancies for the special positions that will be made to this service, and (5) to utilise military surgeons and military assistant surgeons with British and Indian troops under one centralised organisation, tantamount to an amalgamation of these services. This means *REFORM*—and thorough reform

with a stroke of the pen. Yet gently introduced and faithfully adhered to as a policy, it will remove the grievances of India and lower the financial burden of the country in medical matters to an extent that is hardly credible at present.

BALDNESS AND INDIGESTION.

INDIGESTION, that invariable scapegoat, whenever the cause of any disease is obscure, is now called upon to bear the blame of promoting baldness in which it plays only a secondary part. True, careful observance of diet and regularity of meals might prevent baldness, but women who suffer much (their own fault) from digestive troubles are very seldom bald, and we have no evidence that bald-headed men and women are more dyspeptic than their neighbours. Many, and sometimes very far-fetched, are the theories concerning the causation of this condition, the increase of which is co-existent with the general betterment in our social condition; but though nothing is positively known as to the actual causes of baldness, we know that the hair dies that the nobler parts may live up to a proper standard of physiological efficiency, and the majority of opinion inclines to the belief that heredity plays an immensely greater part in baldness than does indigestion.

AN OFFICIAL LANGUAGE.

AN Italian paper announces that a petition, bearing several hundreds of signatures, was lately presented, praying that Latin be made the official tongue of all future congresses. The fact is that the petition referred to was from India, and our readers remember all about it. It was framed by Surgeon-Colonel R. TEMPLE WRIGHT, M.D., I.M.S., and was translated into Latin by Miss FLORENCE HOLLAND M.D., of Allahabad, and the *Record* printed and published it at great expense. The *New York Medical Record* thinks that as Latin is too inflexible, modern Greek is the language best adapted for an international medium of communication. Were either of these suggestions to be carried out, it would necessarily preclude thousands of physicians from association with a congress transacting important business in a tongue with which these thousands are not at all acquainted, but it would give a new impulse to the study of Latin or Greek.

COMPANIONSHIP IN CONVALESCENCE.

SOLITUDE is ill-suited to the sick-room, and nothing would be more irksome in slow or tedious convalescence. Now as the approach to health and its arising incapacity must be reckoned with and provided for, unless we would retard or frustrate the whole process of recovery, it has been suggested at this period, to substitute the sick nurse by a genial and pleasant companion or a judicious friend, so as to afford the social advantages best suited to the needs and wishes of the convalescent. This arrangement especially suggests itself where quarantine or isolation is insisted on for some time after recovery from an infectious disease, and is also advisable on medical grounds in those cases of partial recovery that still require supervision for the completion of cure; but in such instances a trained nurse would be the fittest guardian and companion.

ASEXUALIZATION AND CRIME.

As criminal instincts are unquestionably hereditary, and most of the offences against society originate in sexual disturbance, whether in deprivation or excess, Dr. ROBERT BOAL contends that emasculation and ovariectomy are neither vindictive nor cruel, but that it would certainly exert a deterring influence by limiting the reproduction and transmission by heredity of the defective and criminal classes, and by inflicting a terrifying and abhorrent penalty without destroying life. It would, however, be extremely difficult to get such a law upon the statute books.

THE M. B. DEGREE OF BOMBAY.

In the effort probably of maintaining her proud motto of "Prudentia Fides", and relieving the Bombay College of the charge that the percentage of failure for the higher M. B. examination is abnormally high, because untrained and ill-prepared students get through the earlier tests, which their defective knowledge of English has prevented their properly qualifying for, the Bombay Senate contemplates raising the standard of preliminary general education. But as it unfortunately leaves the all-important preliminary instruction in science in its present unsatisfactory condition, Dr. K. N. RAMADURI points out that it throws a heavy burden on impending medical students by placing them in the awkward position of learning algebra by beginning at equations or surds and indices, or of studying Euclid by starting at the last proposition of the first book. He pleads for a more intimate tuition than formerly, in physiology and histology, without which it is impossible to properly study disease or differentiate diseased from healthy organs, and very naturally wants to know how on earth the Senate can expect to satisfy its incessant cry for "high preliminary culture" without insisting on or affording efficient and practical instruction in the really useful and valuable subjects of biology, chemistry and physics—a sound knowledge of which, not only saves the student's time, but also enables him to earn a high and well-deserved medical degree, as well as facilitates his after-career as a successful physician. He therefore argues the folly of beginning reform at the wrong end, and thinks it were "better far that the present L. M. S. remained undisturbed, than that a fictitious M. B. rise in its place with a P. E. set-off to its shallow and superficial instruction in the scientific and medical course of study."

THE INDIAN MEDICAL SERVICE: A BITTER CRY.

EXPERIENTIA DOCKY writes to the *British Medical Journal*:—"You will be deserving of the everlasting gratitude of young medical men contemplating a career in India, if you will inform them of the following facts, which I make after some years' personal experience in India:

1. The value of the rupee is now 1s. 0½d. (one shilling and a half-penny), and is likely to be less.
2. Two hundred pounds a year in India equals 820 rupees a month.
3. It is absolutely necessary to keep a horse, owing to the relaxing climate.
4. Private practice, except in the very large towns like Bombay and Calcutta, would not pay one's house rent.
5. A medical man, even as a bachelor, cannot live in anything like decent comfort, all reasonable expenses included, for less than 10 rupees (equal to 10s. 6d.) daily; while for a married man without capital it would be impossible; he would be much better off as an assistant in England.
6. The mortality amongst Europeans is just double what it is at home, and when cholera breaks out, the deaths are one in two of those attacked.
7. There are no poor houses in India where a destitute man may seek a refuge.
8. Life in India is not only one of exile, but it is mostly glamour, and of the artificially exalted order, without any real substantial advantages that can be compared with home life." Bravo! So much the better for India.

THE SHORT STORY AND NERVOUS DISEASE.

MONOTONOUS humdrum goodness is without charm, and the utmost tact is required to rouse the nervous invalid from brooding over his sickness, (whether real or imaginary) into taking an interest in his surroundings. One way of changing

the current of unpleasant thoughts, is to present in brief and attractive form, the original and surprising or amusing thoughts of others. This is best done by the short story of the *Harte* style, which unconsciously performs a sort of semi-medical work by capturing the patient's attention without straining it, and leading to a discussion of plot, possibilities, probabilities and character; that, rousing the patient's interest even for a little while, distracts him for the time being from the nervous brooding that might otherwise kill him.

TO BLOW OR WASH THE NOSE.

ACTING as a sieve or filter to the air, as we breathe, our noses become loaded with all sorts of nastiness which sometimes predispose to nasal diseases. The question therefore arises whether we should wash or blow our noses? Our contemporary, the *British Medical Journal*, discovers that the efficacious part of many of the lotions used in nasal affections consists not in the medicine, but in the water they contain. He therefore recommends every one to wash his nose every day by plunging his face into a basin of clean water and taking slight sniffs, in and out, while under water: thus filling and emptying the nasal cavities several times, and cleansing them from the filth contained in them.

STRAINING AND OVER-TAKING OF THE HEART IN ATHLETIC EXERCISES.

THAT athletic exercises, when carried to an extreme, are not free from danger, is amply shown by the investigations of M. TEISSIER, who found that in two-thirds of the subjects examined the patellar reflexes disappeared and the faradaic excitability decreased; but the galvanic contractibility increased, while general fatigue and overtaxing of the muscles, toxic products in the blood, and albuminuria with increased urea, manifested themselves in an appreciable, though variable, degree. The arterial pressure was lowered at least six centimetres, the apex of the heart was lowered, and deviated a little to the right, and the cardiographic outlines showed the brevity of the systole and the sharpness characteristic of the "forced heart beats" described by M. PITRES.

NO FAITH IN INDIAN INCINERATORS.

SAYS *Indian Engineering*:—"A Special Committee has recommended the burial of all garbage collected within the precincts of the Municipality for some years, until incineration or some other method of disposal has proved successful in India. This seems to be a judicious measure for a town like Rangoon, surrounded by vacant and suitable ground for such a purpose. Rubbish trucks on the Burma State Railway carry the town refuse and deposit it 9 miles off."

NEW MEMBERS OF THE INDIAN MEDICAL ASSOCIATION.

We have pleasure in publishing the names of the following gentlemen who have joined the Association since our last issue:—

- Baroda Prasad Mitra, L.M.S., Civil Surgeon, Mahital, Hyderabad Deccan.
 Maruthvan K. C. Duraisami, C.M.S., D. A. Charitable Disp., Pollachi.
 W. Lindfield Brookes, Asst. Surgeon, Hunter Hosp., Saugor, C. P.
 C. K. Maribusoothana Ram, Hosp. Asst., Spl. Asst. Agent's Establishment, Polanaram, Godavari Dist.
 T. Perumalsami Naidu, Hosp. Asst., Civil Disp., Palayam, Godavari Dist.

Medical men and women in all parts of India and Burma who desire to take a share in aiding the advancement of the Indian Medical Association are cordially requested to write to the Editor of the *Indian Medical Record*, and he will gladly send them blank membership forms and prospectuses. We are glad to find many willing volunteers.

IS THE ARMY HOSPITAL NATIVE CORPS USELESS?

"No words can exaggerate their absolute inefficiency, ignorance, recklessness and utter slothfulness. After visiting eight or ten European armies, I have never seen in any army anything to approach them for hopeless uselessness." This is what an experienced Brigade-Surgeon says of the ward servants of the Army Hospital Native Corps. This is a serious indictment, and the worst part of it all is, says a writer in the *Pioneer*, that we know it to be true.

All we can say is that so expert an officer as Brigade-Surgeon Lieutenant-Colonel G. J. H. EVATT, A. M. S., wrote in these columns in high praise of the Army Hospital Native Corps.

SHORT ITEMS.

Dr. Kedar Nath Das, the Registrar of the Calcutta Medical College Hospital, has had the degree of M.D. conferred upon him for the excellence of his paper on "Puerperal Eclampsia" read at the Indian Medical Congress. Dr. Das is an M.B. of the Calcutta University, and a very deserving young man, and we are glad to see, his merits rewarded in a manner that is certainly unique in the history of our Indian universities.

The new jail at Prome is built in the heart of the town close to the Civil Hospital, and as the prison night-soil is trenched in the intervening space for garden manure, the result may be better imagined than described by those acquainted with even the simplest rudiments of sanitation — *Indian Engineering*.

Surgeon-Major Lenhy, I.M.S., takes medical charge of the party which accompanies Prince Nasirullah, the son of the Amir of Cabul, to England. We wonder why a Government doctor was displaced from his office to fill a purely private appointment!

Surgeon-Captain F. O'Kinealy, I. M. S., will take over medical charge of the 6th Regiment, B. L. I., Fort William, from Surgeon-Captain E. H. Brown, I. M. S., who will proceed to Dinapur, and assume medical charge of the 18th Regiment, B. I.

Dr. Dujardin-Beaumetz, the distinguished French therapist, died at the age of sixty-two, on the 15th ultimo at Beaulieu-sur-Mer, where he was staying in the hope to recruit his health.

The appointment of Surgeon-Colonel A. A. Gore, M.D., Army Medical Staff, as Principal Medical Officer in India, has been confirmed. Surgeon Major-General A. F. Bradshaw, C.B., whom he succeeds, is about to be placed on retired pay.

The Hobart Prize has been awarded to B. Mohamed Usman, a student of the Madras Medical College, the only Mahomedan who passed the Second L. M. and S. Degree examination, held in July last.

A new specific for gonorrhoea is a 1 per cent. solution of cresote in decoction of hamamelis combined with boric acid. It is claimed that this will destroy the gonococci in two hours. — *Specific Medical Journal*.

The friends of Surgeon-Colonel Harvey will be glad to hear that he has already benefited by the sea trip. A telegram reports his arrival at Madras in greatly improved health.

Surgeon-Lieutenant R. K. Mitter, of the 18th Madras Infantry, now at Secunderabad, has volunteered to go with the Chitral force, and his services have been accepted. Dr. Mitter actually volunteered three or four years ago for the Chin expedition, but while his offer was accepted, departmental necessities prevented his being actually sent to the field.

Brusque suppression of the drug, giving a hypodermic only in case of syncope, strong coffee four times daily, the heart-strength being kept up with sparteine two grains, and caffeine ten grains daily. — *Votrin*.

Surgeon-Colonel T. Maunsell, Army Medical Staff, has been appointed Principal Medical Officer, Chitral Relief Force, *vice* Surgeon-Colonel W. T. Martin, Army Medical Staff.

Surgeon-Colonel J. H. Newman, M.D., is appointed to be Administrative Medical Officer and Sanitary Commissioner of the Central Provinces.

Surgeon-Colonel W. P. Warburton, M.D., is appointed to be Inspector-General of Civil Hospitals, North-Western Provinces and Oudh, *vice* Surgeon-Colonel J. G. Pilcher, F.R.C.S.

Dr. W. F. Trouson has been appointed to act as Medical Inspector of Seamen in the Port of Calcutta, during the absence, on leave, of Dr. F. K. Butt.

Miss D'Abreu, M.B., O.M., of Tabor, Yarcand, Madras Presidency, has married a gentleman of the name of Mr. Anderson.

We are sorry to hear that Brigade-Surgeon Lieutenant-Colonel H. B. Purvis is going home ill, in anticipation of leave to be hereafter granted to him.

Oleum ricini heated and thoroughly applied to the abdomen of children, will often move the bowels quite as effectually as when given internally. — *Medical Times*.

Surgeon-Colonel D. O'C. Raye, M.D., is appointed to be Inspector-General of Civil Hospitals, Punjab.

Surgeon-Captain Drury has taken over charge from Surgeon-Major Leahy as Civil Surgeon at Alipore.

Surgeon-Colonel A. F. Churchill, Medical Staff, has been appointed an Administrative Medical Officer in Madras.

We hear that Miss Hamilton, M.D., is to accompany the Afghan party to England, in her medical capacity.

Cholera is raging in Calcutta, over 120 deaths occurring last week from this disease.

The public schools of Calcutta are remarkably free from both cholera and small-pox.

The first P. M. O. of the Bengal Command under the new organisation is Surgeon-Major-General T. Walsh, A. M. S.

John Eric Erickson, F.R.C.S., and John Russell Reynolds, M.D., have been made baronets.

Dr. William Huxley has been granted 18 months' furlough to England, and left Kotah on the 15th instant.

VITAL STATISTICS.

* There were 28, 5, and 14 deaths from *Beri-beri*; and 0, 148, and 1 deaths from *Kala-azar*, in these three districts, respectively.

OUR LONDON LETTER.

(From our own Correspondent.)

THE weather, which was intensely cold, has undergone quite a pleasant change, and while our city has been rejoicing in the sunshine, it is somewhat jarred by the outbreak of influenza and a rapid increase in the metropolitan death-rate. This will give our readers some idea of the present state of climatology in England.

DR. F. T. ROBERTS selected as the subject of the Lettsonian lectures, a somewhat novel text, "On the combination of morbid conditions within the chest"; in the course of these able addresses he makes a clever attempt at classifying these conditions: they are, however, reported as *extensive* in our leading English medical contemporaries.

Among the *on dists* may be mentioned the intention of Mr. McDONALD, M.P., to lay a Bill before the House of Commons with a view to restrict the sale of poisons.

Later, many important articles have been written on the subject of typhoid propagation by means of that savoury mollusc, the oyster. Among these may be noted those of Sir W. H. BAODRENT, M.D., and Sir PETER EADE, M.D., who seemed to think that the oysters became infected by *Escherichia bacillus* while lying in estuaries, just where rivers join the sea, and where it may be stated as a broad

rule that some large main sewer discharges its voluminous contents! This, of course, may be so or not, but many cases of typhoid fever have been apparently traced to such a source. The matter created quite a stir in many circles. In our opinion nowever, we should be inclined to say that the water in which the bivalves were *last* washed, was tainted by sewage containing these particular bacilli. While we are thus running on the subject of *typhoid*, it is reported that some famous Italian experimenters have discovered and demonstrated this self-same bacillus in a far more widely used commodity of food, *viz.*, butter. Another table article, *viz.*, watercress, has come in for its share of suspicion, probably with even more justice than the luscious and succulent oyster. Watercresses, as sold in our London streets, are a most likely means of distributing pathogenic microbes, and this we are even constrained to admit. This vegetable is mostly grown in waterbeds connected with rivers and streams, many of which are only too likely to be contaminated by sewage. Again a large quantity of watercress is grown wild in all kinds of insanitary localities, such as stagnant pools and ditches. It may be delivered as an *assured* axiom, that all water-growing plants are liable to collect a variety of organisms and parasites, due in most instances in this

case, this is not the case. Further, the vegetable is eaten raw, and does not therefore pass through the sterilisation stage of boiling as does much of the human-cooked food, and this sort of boiling it is (as has been hinted by more than one authority, Dr. PATER, &c.) that safeguards man against the organisms of disease in a great measure; it certainly reduces risk in a marvellous degree. Another point may be put forward as follows: The typhoid bacillus external to the body has great adaptability to its environment, and becomes a hardy microbe. Based on theoretical grounds alone, there is no doubt that enteric fever may be spread by the ingestion of sewage-contaminated watercress. Some bacteriological evidence has come to hand, but more such evidence and confirmatory facts must be brought to light ere we might deem it politic to accept these theories as established scientific facts. Doubtless, the key to public safety from a sanitarian's point of view is thorough and searching inspection of all articles of public food. A shrewd contemporary remarks "that it is only by the logical and thorough application of the discoveries of modern science, that England has gained her proud position as the foremost nation in the world in the section of sanitary administration and reform." The dailies which are busy discussing the above and cognate matters, by their tone and attitude, demonstrate the vast interest aroused in all classes touching sanitary reforms.

A party of lay journalists have written what they imagine to be scathingly acute criticism on what they term "so-called medical progress," stigmatising antitoxin as a filthy remedy, without any really clear perception of the why? or wherefore? These pseudo-scientific faddists virtually call down the vengeance of man and Heaven on the experimental physician, who laboriously devotes his days and nights to studies calculated to advance medical knowledge, especially in regard to diseases hitherto regarded as almost incurable. These men are like thistle down before the wind. The watchword of the medical profession ever is, and should be, "excelsior," and these lofty minds may well despise the frenzied outbursts of those who are like the broken reed, and who fall by the weight of their own scurrilous invectives.

At the Workop County Court, a woman claiming to be agent for Count Mattei's so-called remedies, sued a number of persons to recover the price of the same supplied to them by her. His Honor sent the bottles handed in to him for analysis; the County analyst reported that their composition was mere tap-water. Judgment would have been given for plaintiff, but she suddenly withdrew all the actions.

Mrs. GOSLETT has been lecturing under the auspices of "the Dublin Public Health Society" in various parts of Ireland. She is an Associate of the Sanitary Institute. These lectures and the unostentatious work of this little Society, so unobtrusively performed, have accomplished more practical good in Dublin than all sanitary legislation.

Small-pox has assumed somewhat alarming proportions: there being 28 fresh cases in the course of a week with 11 deaths. The guardians have strenuously opposed the adoption of precautions. The medical authorities are looking tight in regard to this serious matter.

Statistics show that there are 600,000 drunkards in England, and that £14,000,000 is yearly expended in

alcoholic beverages, and an equally serious side to the same matter is one which has never been submitted to searching enquiry, viz., the elaborations of those same beverages.

The following is the report of a death during anaesthesia produced by nitrous oxide administered for the purpose of extracting a tooth:—The patient, a girl of 18, recovered consciousness after anaesthesia in about 2½ minutes, but syncope supervened in spite of all they could do, and she died. On post-mortem it was found that her waist and the skin measured 28 inches, although her stays were laced to 18 inches! Liver weight was 9 ounces above normal; it was compressed transversely, left side of heart contracted, right heart dilated.

We have just been chatting over the typhoid question and *apropos* sanitary matters. The last volume of STEVENSON and MURPHY'S comprehensive treatise on public hygiene has just come out. In this section, the public health law of England, Ireland and Scotland is here collected and analysed in such a way, that it goes far to dispel the mysterious intricacies of sanitary law by explaining these points as clearly as possible for the edification of medical men. The editors have sought the co-operation of authorities who are specially engaged in sanitary law work. It is divided into sections. The first deals with law relating to public health in England and Wales; the second with the same subject in relation to Ireland. The third with the sanitary law of Scotland.

MR. JONATHAN HUTCHINSON has revived the publication of his famous "Archives of Surgery;" volume 6 has appeared. This contains a chronology of medicine and surgery from the 15th to the 19th century.

We are told that a discussion on the subject of re-vaccination is imminent: the theory at present suggested is to fix the age at which revaccination should be performed in children, at 12 years, or if there is danger of their being brought into immediate contact with small-pox, the procedure might then be carried out in their 10th year of age, but not earlier.

Much acrimony has been evoked on the score as to whether diplomas should be granted to midwives or not.

DR. GOONSHIR, whose name was brought prominently before the world in connection with the Arctic Expedition for the relief of the *SIR JOHN FRANKLIN Expedition*, (1849) has just died. After wandering through Australia, the South Seas, Russia and Siberia, he returned to Edinburgh, where he has lived in retirement, known only to a small circle of friends. He passed away at the age of 71 years, after a most adventurous life.

THOMAS GORDON HAYE, M.D., who has been better known as a poet than a physician, being the author of "Vates" (1859) was one of the associates of Dante, Gabriel Rossetti, &c. Other works from his pen were "Madeline Parables and Tales &c.," "The Serpent Play &c." He has also published memoirs of 80 years in 2 volumes. He died in London at the age of 86.

Surgeon-General JOHN JAMES CLARKE died at Melbourne. This officer entered the I. M. D. in 1858, retiring with his present rank in 1884. During the Indian Mutiny (1857 to 1859) he served with the artillery under Generals Havelock, Guthrie and Nelly, being present at the actions of Bithoor, Mungwar and Alumbagh. At

the first relief and defence of Lucknow Residency he took part; and was also present during the operations in Oudh, (furnished with 2 clasps.) He also served in the Akha Expedition in 1883-84 as P. M. O., and was awarded a good service pension in 1882. Just a word on another of the deceased worthies of the A. M. D., who have seen service in Hindoostan, viz., EYRE CHAMPION DE CRESTONY, M.B., late of the Bombay service. He has just died in retirement at Beckenham.

The ex-Khedive of Egypt, ISMAIL PASHA, has died in exile.

"The Church Army" have established a free dispensary for women and children (Crawford St., W.). A lady physician is in attendance twice a week to carry on this charitable work.

A small colony of about 40 lepers has been formed at Villuisk, Eastern Siberia, the Russian Government granting an annual subsidy (7,000 roubles), ample enough for the support of 100 of these afflicted beings.

The Right Honorable WILLIAM EWART GLADSTONE has been enjoying excellent health during his visit to the Riviera.

H. M. Queen Victoria is on her way to Italy. Her Majesty has generously contributed £25 to the fund in aid of building-extension connected with the Miller Hospital, Greenwich.

A renowned ladies' doctor was summoned to Monte Carlo by the widow of a millionaire coal-owner. The man of physic has returned to London the richer by a fee of 700 guineas! The *thyroid gland tissue* is still largely prescribed as an active remedy for of myxoedema, exophthalmic goitre, psoriasis, &c., &c.

Messrs. OPPENHEIMER and Co., 14, Worship Street, have further developed the manufacture of their "Bi-Palatinoids" by adding to their number such volatile drugs as ether, chloroform, hydrocyanic acid, chlorodyne, &c. These are remedies of every-day usage, hence their exhibition in this new form, combining purity, portability, and potency with *exact* dosage, (a difficult matter where *volatility* is concerned) will no doubt be welcomed by the medical world meeting, as they do, a distinct want in this direction.

Current Medical Literature.

MEDICINE.

Diagnosis of Pleuritic Effusions.

DULX considering the uniformity of dynamic conditions under which fluid collects in different pleural cavities, H. B. WHITNEY, Esq., M.D., infers *a priori* that such collections have a uniform characteristic shape determinable by percussion and furnishing evidence of a pathognomic, and *more* conclusive character than that obtained by other physical signs, which, though of great value, are not pathognomic; while the other commonly received signs of effusion are for the most part equivocal, and even *vocal fremitus* is of uncertain import.

This characteristic feature is the curve of the upper boundary of *flatness* as elicited by light percussion along a line beginning at the spine, running horizontally for a varying distance, and then dropping by an abrupt curve to the base of the thorax. This curve takes the shape of the letter S, and the larger the effusion, the wider the zone, and the more

anterior the drop—the latter, sometimes, but not always, above the base as far forward as the apex of the heart. This curve can easily be defined by gently tapping and gradually moving the pleximeter finger from the area of absolute flatness toward the area of resonance, and making a mark as soon as the slightest resonance is perceived. Good pulmonary resonance, immediately above this line must not be reflected, and while the slight compression of the whole lung further diminishes the resonance, giving the percussion note a higher pitch and slightly tympanitic quality, resonance over the scapula is never great, and the space between the S curve and the spine ("Garland's" *dull triangle*) is often so dull as to escape recognition, and this important sign of pleuritic effusion may be passed unnoticed by the not over-attentive observer.

The treatment of Dysentery.

SURGEON-MAJOR S. T. AYETOO, of the 1st Baluch Battalion, L. I., sends us the following communication:—"I wish to bring to the notice of the profession a new treatment for acute dysentery. It is not original, but was obtained from a medical work in Persian. This is what the book stated (I translate):—"Treatment for acute dysentery: Reduce cinnamon bark to a fine powder, take one and a half drachms, mix it with a little 'mallai' (the cream which gathers on the top of boiled milk after it is allowed to settle and cool), and administer in the morning on an empty stomach. The patient will be cured. I have made a slight alteration in the above. The powdered cinnamon is given in drachm doses only, mixed with a few drops of water and made into a ball, which is given to the patient to eat, washed down by a mouthful or two of water. This quantity is repeated again in the evening, and so on, morning and evening, until a cure is effected. It is a little over two years since I started this method of treatment, and have cured about thirty cases of the disease. Often patients have been cured by only one or two doses of the drug, while my worst case was cured after five doses only, but a sixth was given to make quite sure. This method of treatment is vastly superior to the ordinary ipecacuanha treatment, in that the medicine is pleasant to take and causes no nausea or vomiting, and acts, if anything, quicker and better than ipecacuanha. If the drug were given in drachm and-a-half doses as recommended in the book, most probably cures would be effected more quickly, but my method has been quite quick enough. The earlier the treatment is begun the quicker the cure."—*Lancet*.

Landmarks of Visceral Disease.

PERITONITIS, which is nature's method of repair, produces exudates, which bury and starve the invading germs—deadly germs—yet it is only a secondary matter, and being resultant on traumatism or disease of the viscera. The *great* peritonitic districts are (a) the pelvis, (b) the appendix, and (c) the gall-bladder; while among the *minor* districts may be classed inflammation round sphincters and along or around the flexures of the colon. DR. BYRON ROBINSON'S autopsies have shown that ALBES had a good deal of truth on his side, when over two generations back he said: "The coccum is the disturbing element in man's trouble in the right iliac fossa;" for the majority of the cases lying on the psoas and iliac muscle which contract and relax during walking, and the irritation caused by these continual movements (during walking) will, if the coccum be congested or inflamed, produce a chemical or mechanical peritonitis, causing exudates which will organise and result in the bands, dense adhesions, and thick new fibrous tissue, so frequently found under the place where the sigmoid crosses the psoas muscle and around the coccum.

Dysentery and Diseases with Complications.

F. S. MORVAN, reports the case of a girl of 30 years. When first seen, she had hydrocephalus; blue, mottled patches on face, legs, arms and back, extreme lividity, nasal gangrene of second toe of both feet, and little or no pain. During the next 74 months she seemed to improve, but three weeks later, she got decidedly worse, constantly complaining of severe pain and a dark blue, almost black, spot is present on each cheek. The hands, wrists, back and hip are of a reddish color. A swelling that made its appearance a little above the sternum, proved to be a diverticulum of the trachea, in the walls of which a vertical slit could be felt. The second toe of left foot is decidedly worse, and of a pure blue color. The urine is free from albumen, blood and sugar, and there is nothing abnormal about the heart. Fever, urticaria, scleroderma, clubbing of the fingers, muscular palsy or wasting and anaesthesia, and swelling of the joints, are all of them absent.

Epilepsy and Typhoid Fever.

In exemplification of the influence of intercurrent ailments upon the frequency of severity of the attacks in epilepsy, **DR. LANNONIS** records the case of a woman who, in consequence of infantile hemiplegia, had become a manifest epileptic since childhood. She first suffered from erysipelas of the thigh followed by typhoid fever. While the erysipelas lasted, the frequency of the fits was considerably lessened, but during the typhoid attack it was greatly increased. He thinks the modification of these attacks depends not on the pyrexia of the febrile, but on the nature of the specific poison, which may either lead to the total or partial suppression of these fits for a time, or increase their frequency.

Morvan's Disease and Leprosy.

WHILE he admits that in some cases of leprosy there may be symptoms closely analogous to those found in some cases of MORVAN'S disease, **M. GOMBAULT** points out that neither pathological anatomy nor biological investigations furnish any confirmation of the view held by some writers that MORVAN'S disease, RAYNAUD'S disease and scleroderma are merely varieties of leprosy. **MARESTANG**, who studied the clinical aspects of this question, declares that MORVAN'S disease and leprosy are by no means identical, and GOMBAULT furthermore shows that the changes in the peripheral nerves that characterize leprosy, are not to be found in MORVAN'S disease, of which (latter) syringomyelia appears to be the anatomical substratum.

Endocardial Lesions in Tuberculous Subjects.

AFTER a long and careful study of this subject, **TEISSIER** concludes that in endocardial lesions due to tuberculosis, the form is multiple and the pathology complex; for while the bacillus acts locally by depleting nutrition and creating a specific lesion which does not cause any characteristic cardiac signs, and very rarely shows itself as granular or caseating nodules, the tuberculous influencing the vaso-motor system is especially active in the sclerosing form, which being the result of slow tuberculous infection, occurs during chronic tuberculosis, and shows itself by producing harsh cardiac murmurs and many of the cases of valvular disease; but instead of acting separately, the tubercle bacilli, toxins and associated bacteria all combine to produce the disease.

Hæmorrhagic Nephritis in Diphtheria.

ON the fifteenth day after using **BEHRING'S** serum in a child of 8 years, **TRYMARK** found albumen, blood, and casts in the urine, and pyrexia together with a mealy eruption were noticed. Four days later there was anuria, and oedema about the eyelids, and during convalescence, hæmorrhagic nephritis, but disappeared in an unusually short time. Later, diphtheritic paralysis supervened in this case. **SCHWALBE**, who maintains that great caution should be used in attributing favorable results to the serum treatment, reports a case where he administered "serum" to a child of 10½ years in whom the hæmorrhagic nephritis appeared on the 25th day, and most of the symptoms disappeared in a week.

SURGERY.**Ophthalmia Neonatorum: Its treatment, prevention and necessity for more efficient legislation to prevent blindness from this cause.**

WHILE many recognized the importance of prophylaxis and had tried pre-delivery disinfection of the vagina of the mother and various applications to the eyes of the newborn, **CREON** was the first to use a germicide, and the majority of the maternity hospitals use his method:—(1) Immediately after birth the child's eyes are carefully cleansed with tepid water every half hour or so; but if there is or any discharge, the eye should be cleaned with a solution of either boric acid or of iodine chloride and then irrigated with lukewarm water. (2) One drop of a two per cent. solution of silver nitrate is allowed to fall upon the cornea. (3) Cold or hot compresses if there is much inflammation; and (4) treatment of the corneal complications.

Switzerland was the first (1835) to legislate for the prevention of blindness from ophthalmia neonatorum, Prussia followed in 1878, Austria 1883, France 1888, New York 1890, Maine 1891, Rhode Island 1893, since which, other cities and states have followed suit. The law provides a penalty of \$100 fine or 180 days' imprisonment for that nurse or midwife who having charge of such infant and noticing such a condition fails to report in writing, within six hours if one or both of the child's eyes are reddened at a time within two weeks after its birth. Universal statistics are not available, but if we consider the United States only, where at the last census there were 50,411 blind persons of whom at least twenty per cent. (10,083) were made blind by neglected ophthalmia neonatorum, we cannot but conclude, says **DR. CHARLES H. MAY**, that the law, as it stands, is ineffective, and that instead of reporting cases to any qualified practitioner of medicine who has not the time to dance attendance on the court in cases of prosecution, the law to appoint proper inspectors to enquire into such cases and demand that written notices of the appearance of ophthalmia neonatorum should be immediately reported to the local health officer or local board of health.

Ligature of Carotid Artery for Cerebral Hæmorrhage.

HORSLEY and **SPENCER**, who found that hæmorrhage in the basal ganglia could be controlled by ligature of the common carotid artery, suggested a similar procedure in cases of intractable apoplexy. This operation was lately performed by **DR. DERCUM** and **DR. KEEN** in two cases, one of whom recovered, and the other, who was too far gone at the time, died. The successful case was that of a man of 50, who on the morning of the 11th February noticed a slight weakness of left arm and in the evening a similar condition of left leg. This one-sided weakness daily increased in such large strides, that on the fourth day there was complete motor palsy of left arm, decided weakness of left leg, paralysis of lower half of left side of face, giddiness, a dull feeling in the head, but no headache or obscuration of intelligence. Albumen was present in the urine in small quantity. The right common carotid was ligatured under the influence of cocaine alone, with an appreciable improvement in the patient in two days' time. He is now able to freely move his left hand and fingers, and there is very little weakness remaining in the affected parts and no anaesthesia. In the other case the weakness began at 2 P.M. in his left arm, and towards evening had involved the leg and face of same side, but paralysis having deepened and unconsciousness supervened during the night, ligature of the carotid failed to relieve him, and he died a few hours later.

and pelvis, and the bladder, which was dilated, hyperemic and congested, and the uterus lying as though down to the lowest impossible in some parts, occupied an abnormal and adherent blood-clot of the size of a large hen's egg. The right kidney was much enlarged and contained several small abscesses, and its pelvis was greatly damaged by extensive ulceration; but there was no appearance in the water of blood staining.

Notes on Pelvic and General Massage.

DR. SARAH M. POST writes that pelvic massage gave her very satisfactory results in propelling the contents of the tubes down through the uterus and securing their discharge without the usual recurring tubal colic, which appears to be due to traction upon the peritoneal attachments in the inguinal region. She thinks that massage is also useful in simple one-sided tubal catarrh. In her opinion the "down stroke" in the usual long rub during the course of a bath is not advisable, as it slows the heart pressure, causing unpleasant sensations, whereas "up" rubbing produces a slowed, strengthened, comfortable pulse, and will be found useful in cyanosis, pulsating jugulars and an overloaded heart.

Vaginal Hysterectomy.

EDBOLLS contends that enucleation of the uterus with ligature of the bleeding vessels only, is the ideal method, and as all further constriction or crushing of tissues is harmful, he utterly discards the French practice of clamping and the German serial ligation of the broad ligaments, except in cases of extensive malignant disease, when it may be necessary to give the uterus as wide a berth as possible.

When shall we operate for Pyo-Salpinx?

IN reply to this burning question that has for a long while perplexed the surgical faculty, DR. CHARLES N. SMITH finds that the most favorable time for operation is after pus-formation in the tube, and before the occurrence of extensive peritonitis. Such opportunities are not however often presented, as in the first place it is not easy to convince people of the danger of these conditions and the necessity for immediate operation to avert the absolute certainty of a more serious condition that may follow, and secondly, peritonitis is either coincident with, or very quickly succeeds the salpingitis, and the whole pelvis becomes blocked by a firmly adherent mass of pus-tube, ovary and bowel. Three alternatives are open to the surgeon: (1) watchful expectancy for the subsidence of the inflammation and diminution in the size of the mass before enucleation, (2) immediate operation with its attendant risks, and (3) puncture either through the rectum or vagina—the latter most often—evacuation of the pus and efficient drainage, which appears to be a much better procedure than laparotomy, even though the latter operation is advised and successfully performed in many such cases by our most prominent gynecologists.

Kraurosis Vulvae.

As cautery, narcotic injections, poultices and baths do but little good in this painful and atrophied condition, MARTIN declares in favor of excision of the diseased tissues together with a small portion of their healthy margins, and subsequent sutures. Eight cases that he treated suffered from dysuria in addition to the leucorrhoea which was accompanied with itching, burning, burning sensations about the vulva, a weak feeling of tension during defecation and micturition, and certain cases absolute pain. While in some cases ugly tumors developed and the pain then, becoming constant, the general health failed.

Ecstasy Generation.

DR. WARRAN does not include sexual pregnancy under this condition, which he divides under three heads: (1) *Ampulla*, which is the most common and beginning in the ampulla of the tube may, in rare instances, go on to full term; or (2) *rupturing into the broad ligament*, it may continue to develop as subperitoneo-pelvic, subperitoneo-abdominal, tubo-ligamentous, extra-peritoneal or broad ligament gestation terminating by hematoma, suppuration, metamorphosis and malppearance or lithopneum formation; (3) *rupturing into the peritoneal cavity*, it may continue as tubo-peritoneal gestation, which may terminate in any of the above ways, or a hematoma-cyst forming, the patient dies either from shock and loss of blood, or from peritonitis; or (c) *the gestation may be destroyed* by tubal abortion or absorption by metamorphosis, etc., after early death, or by the formation of a mole, or a hematoma-plux, or by suppuration resulting in pyosalpinx. (2) *Inter-tubal*: starting in the intertubal portion of the tube. It may go on to full term, or may go on to the same period after rupturing into the layers of the broad ligament, or into either or both the uterine or peritoneal cavities, or the fetus may die early and remaining in the mass, undergo the same changes as in the other forms. (3) *Infundibular*: beginning in the outer end of the tube, or in an accessory tube-entail, merely becoming adherent to the abdominal wall, the ovary or other of the viscera.

—10—

PHYSIOLOGY, PATHOLOGY AND BACTERIOLOGY.

Commensalism, Parasitism, and Symbiosis.

WHEN one organism lives in or upon another merely for the purpose of preying upon it, it is termed a *parasite*, but when a mutual or physiological partnership is formed between two beings, the condition is termed *symbiosis*, in which the partnership may exist between two animals or two plants, or one may be an animal and the other a plant, and in some cases the association is so close, that it is almost impossible to determine whether they are two beings or one only. For instance, the minute yellow algae that inhabit radiolarians appear part and parcel of the latter, but can live independent of them; yet while they are together, they continuously exchange compliments, for the algae evolve oxygen, which supplies the chief wants of the radiolarian, which in its turn gives off the carbonic acid and acidized products necessary for the food of the former, and each is protected by the other's company. The term *commensalism* is applied to those cases where the union is much less intimate, though host and great reciprocal services as in the case of the sea anemone, which attaching itself to the shell or claw of the hermit-crab, gets its conveyance free and shares the feast whenever the crab feeds; but he helps the crab in killing or numbing his prey, *hides him when danger threatens*, and carefully assists him in changing his shell when the time comes to throw off the old one. Thus then by showing us the marked interdependence of lesser organisms, these Nature prove to us that we serve ourselves by serving others, and that few indeed, if any, are able to live for and by themselves.

The Compensatory action of the Cerebral Hemispheres.

It is recorded that in left hemi-cranial with impaired speech and writing, the left hand could write better during the attack than after, and in order to demonstrate the compensatory or vicarious action of the inter-cerebral hemisphere during deep sleep, HALLER and MARKOWITZ observed, that sleep

and surface of the tubule, which was dilated, hyperemic and extremely congested, and the mucous lining as smooth as if no almost impossible in some parts, contained an organized and adherent blood-clot of the size of a large hen's egg. The right kidney was much enlarged and contained several small abscesses, and its pelvis was greatly damaged by tuberculous ulceration; but there was no appearance in the water of blood staining.

Notes on Pelvic and General Massage.

DR. ALVAN H. FOST writes that pelvic massage gave her very satisfactory results in propelling the contents of the tubes down through the uterus and securing their discharge without the usual recurring tubal colic, which appears to be due to traction upon the peritoneal attachments in the inguinal region. She thinks that massage is also useful in simple one-sided tubal catarrh. In her opinion the "down stroke," in the usual long rub during the course of a bath is not advisable, as it slows the heart pressure, causing unpleasant sensations, whereas "up" rubbing produces a slowed, strengthened, comfortable pulse, and will be found useful in cyanosis, pulsating jugulars and an overloaded heart.

Vaginal Hysterectomy.

EDMONDS contends that enucleation of the uterus with ligature of the bleeding vessels only, is the ideal method, and as all further constriction or crushing of tissue is harmful, he utterly discards the French practice of clamping and the German serial ligation of the broad ligaments, except in cases of extensive malignant disease, when it may be necessary to give the uterus as wide a berth as possible.

When shall we operate for Pyo-Salpinx?

IN reply to this burning question that has for a long while perplexed the surgical faculty, DR. CHARLES N. SMITH finds that the most favorable time for operation is after pus-formation in the tube, and before the occurrence of extensive peritonitis. Such opportunities are not however often presented, as in the first place it is not easy to convince people of the danger of their condition and the necessity for immediate operation to avert the absolute certainty of a more serious condition that may follow, and secondly, peritonitis is either coincident with, or very quickly succeeds the salpingitis, and the whole pelvis becomes blocked by a firmly adherent mass of pus-tube, ovary and bowel. Three alternatives are open to the surgeon: (1) watchful expectancy for the subsidence of the inflammation and diminution in the size of the mass before enucleation, (2) immediate operation with its attendant risks, and (3) puncture either through the rectum or vagina—the latter most often—evacuation of the pus and efficient drainage, which appears to be a much better procedure than laparotomy, even though the latter operation is advised and successfully performed in many such cases by our most prominent gynecologists.

Kraurosis Vulvæ.

As caustics, narcotic ointments, poultices and baths do but little good in this painful and atrophied condition, MARTIN declares in favor of excision of the diseased tissues together with a small portion of their healthy margins, and subsequent sutures. Night cases must be treated suffered from dysuria in addition to the kraurosis, which was accompanied with itching, burning, burning sensations about the vulva, a weary feeling of tension during defecation and micturition, and actual, incessant, absolute pain. While in some cases ugly tumors developed and the pain then, becoming constant, the general health failed.

Embryologic Speculations.

DR. WHEATON does not include animal pregnancy under this condition, which he divides under three heads: (1) *Asphyxial*, which is the most common and beginning in the amnion of the tube may, in some instances, go on to full term; or (2) *rupturing into the broad ligament*, it may continue to develop as subperitoneo-pelvic, subperitoneo-abdominal, tubo-ligamentous, extra-peritoneal or broad ligament gestation terminating by hematoma, suppuration, mummification and adiposcent or lithopelion formation; (3) *rupturing into the peritoneal cavity*, it may continue as tubo-peritoneal gestation, which may terminate in any of the above ways, or a hematocoele forming, the patient dies either from shock and loss of blood, or from peritonitis; or (c) *the gestation may be destroyed* by tubal abortion or absorption by mummification, etc., after early death, or by the formation of a mole, or a hematoma, or by suppuration resulting in pyosalpinx. (2) *Interstitial*; starting in the interstitial portion of the tube, it may go on to full term, or may go on to the same period after rupturing into the layers of the broad ligament, or into either or both the uterine or peritoneal cavities, or the fetus may die early and remaining in its mass, undergo the same changes as in the other forms. (3) *Infectious*; beginning in the outer end of the tube, or in an accessory tube-entail, merely becoming adherent to the abdominal wall, the ovary or other of the viscera.

—0—

PHYSIOLOGY, PATHOLOGY AND BACTERIOLOGY.

Commensalism, Parasitism, and Symbiosis.

WHEN one organism lives in or upon another merely for the purpose of preying upon it, it is termed a *parasite*, but when a mutual or physiological partnership is formed between two beings, the condition is termed *symbiosis*, in which the partnership may exist between two animals or two plants, or one may be an animal and the other a plant, and in some cases the association is so close, that it is almost impossible to determine whether they are two beings or one only. For instance, the minute yellow algae that inhabit radiolarians appear part and parcel of the latter, but can live independent of them; yet while they are together, they continuously exchange compliments, for the algae evolve oxygen, which supplies the chief wants of the radiolarian, which in its turn gives off the carbonic acid and azotized products necessary for the food of the former, and each is protected by the other's company. The term *commensalism* is applied to those cases where the union is much less intimate, though host and guest reciprocate services as in the case of the sea anemone, which attaching itself to the shell or claw of the hermit crab, gets its conveyance free and shares the feast whenever the crab feeds; but he helps the crab in killing or numbing his prey, hides him when danger threatens, and carefully assists him in changing his shell when the time comes to throw off the old one. Thus then by showing us the marked interdependence of lesser organisms, *Nature* prove to us that we serve ourselves by serving others, and that few indeed, if any, are able to live for and by themselves.

The Compensatory action of the Cerebral Hemispheres.

It is recorded that in left hemiplegia with impaired speech and writing, the left hand wrote better during the attack than after, and in order to demonstrate the compensatory or vicarious action of the undiseased hemisphere during deep sleep, MARTIN and MATHISON, opined, that sleep,

is most profound during the first two or three hours, and that as during working hours the strain falls on the right hand, and speech was controlled by the left cerebral hemisphere, the latter would be more exhausted and less accessible than the right, to stimuli during sleep. She found that on tightly twisting either side of the face of the ordinary sleeper, he or she made repellent movements with the left hand invariably, even when lying on the left side, and having to withdraw the hand from under the body; but left-handed persons moved the right limb.

Excretion of Toxic Products.

THE idea hitherto obtained that the toxic substances in acute and chronic disease are *alkaloids* derived from piperidin, but ALBY, who complains of the difficulty of searching for these poisonous products in the excretions (as such large quantities of urine have to be used), says that he found *poisonous alkaloidal substances* in seven cases only (*viz.*, phthisis 3, Graves' disease 2, tetany 1, and pernicious anemia 1), of the many he examined, while the alkaloidal substances found in three cases were not at all poisonous. He points out that a large number of the decomposition-products of albumen have no specific significance when excreted by the urine, and acetone is often a harmless manifestation, but at other times most serious symptoms present themselves, and unfortunately very great difficulty attends the chemical representation of the toxic products of disease.

The Chemical Pathology of Uræmia.

IN a recent experimental study of uræmia, HUGHES and CARTER have contributed to the pathology of this important condition (*Amer. Jour. of the Med. Sciences*). They conclude that there is one poison present alike in uræmic human blood, in dropsical effusions in uræmia, and in dog's blood in experimental uræmia; and that this poison is not one of the ordinarily recognised constituents of the urine, as generally believed, but one whose nature or even existence has not before been recognised. The facts that its action is much lessened after subjection to moderate heat, and that it is not readily dialyzable, seem to indicate that the poison is an albuminous body; while clinical evidence indicates that it is not a constant constituent of the blood, but produces the uræmic condition by accumulation, owing to the inability of the kidneys to excrete it, or more rarely by a sudden and enormous production. The order in which serums stand as to their toxicity, proceeding from the most toxic to the least is, man's, the dog's, the horse's. This suggests to the writers that the origin of the substance is to be traced to the character of the food, which is more nearly carnivorous with man and the dog and purely herbivorous with the horse, and that its production takes place somewhere in the digestive tract. —*N. Y. Med. Record.*

Bacteriology of the Healthy Conjunctiva.

AS the results of experiments made on himself with *Micrococcus candidus*, *Bacillus sporiferus*, *B. fluorescens putridus*, *S. pyogenes albus*, *M. coronatus* and *M. cereus albus*, to determine the effects of microbes penetrating into the healthy eye, S. LACHOWITZ proves that the inoculation exerts neither subjective nor objective phenomena, and that the bacteria completely disappears from the eye within 24 hours after the inoculation.

Bacteriology of Cholera.

KOCH points out that the pathologist has two methods of examination open to him: (1) the naked eye, by which the typical cholera bowel may be seen, injected on both sides, but with large patches of mucous membrane completely denuded of epithelium, and rice-water-like fluid, whilst the typical

cholera stool consists of the same fluid in which the typical flakes are deposited; and (2) the bacteriological, in which one, who has to diagnose cholera bacteriologically, must never give up the examination unless he has been able to acquire the constant practice and the full mastery of the technique of bacteriology essential for the work, as elements of doubt often arise from the unpracticed eye being brought to bear on material that very often widely differs in appearance from that of the true cholera stool, consisting in scanty matter, and containing "mucus flakes" instead of the usual "epithelial debris" with but few comma bacilli; while at other times, the material is indistinguishable bacteriologically, from that of true cholera, and again in other samples, the bacilli may be found in overwhelming numbers, yet so thickly mixed up with other disease germs, as to require considerable patience, care, and skill to properly separate and differentiate.

PUBLIC AND DOMESTIC HYGIENE AND JURISPRUDENCE.

Car Ventilation.

IN order to guard against draughts while provided for better ventilation in railroad cars during winter, when the bitter cold necessitates jamming up every possible crack that the biting wind can enter through, and consequently does not provide for the escape of vitiated air from the interior of the compartment, the Master Carbuilders' Association, U. S. A., wish to devise an apparatus that, irrespective of whether the train is moving or standing still, will admit 30 cubic feet of fresh air per passenger per minute, and carry off an equal amount of foul air at the same time. The fresh air so admitted must not come in quicker than at the speed of 4 miles per hour, nor exceed 70°F, nor again be too dry during winter, and arrangements be made for the equal distribution all over the car of this admitted air. In summer the same quantity and speed of air will be required, but the temperature and humidity will be controlled by climatic conditions at the season obtaining.

The Dangers of Street Penny Toys.

FROM England comes a note of warning against the dissemination of tuberculosis by vendors of penny toys, especially those which require inflation to emit sounds or take fantastic form: the method of doing which is exhibited for public bait by the street vendors, many of whom are fitter subjects for the hospital—consumption or otherwise—than for road peddling. We would be remiss in our duty were we to not extend this warning note to India, where the purveyors for the mighty "pice" are not over particular as to their phthisical sufferings, and utterly discard cleanliness of person, &c.; considering the possibility of this easy mode of transferring horrible diseases and the appalling certainty of direct microbial infection, we raise no mere passing scare but point out a most serious danger requiring legal supervision to control and prevent the spread of small-pox, phthisis, scarlet fever and other highly contagious diseases to which our little ones are subjected, whenever we patronise the doubtful wares of the peripatetic proprietor.

"What should be classed as Dangerous Infectious Diseases?"

FORMS the subject of a very interesting paper read before the Congress of the Sanitary Institute, Liverpool, by Dr. JOSEPH PHIBBS, who divides these diseases into two classes:—(1) *Dangerous infectious diseases*, which require for their prevention usual stringent measures for notification, isolation, disinfection, quarantine, medical inspection and

nasal douche or gargle with chlorate of potash and bicarbonate of soda.

Mustard oil has long been known as a deodorant; but *ROSWALL PAIN*, who finds that the ordinary flour of mustard is just as well, recommends it in all cases where foul wounds or discharges have been touched or where other deodorants cannot be obtained. Noting also that while diluted morphine solutions form good culture media for bacteria, pathogenic forms cannot grow in syrups or concentrated solutions, he regards sugar as an useful antiseptic, and suggests its application to surgery, stating that he has used powdered sugar with very good results in compound fractures.

Phenacilin in 10 to 15-grain doses very often relieves acute sciatica and makes the patient feel quite comfortable, but if the pain is severe, injections of morphine will thoroughly arrest it.

Lanoline melting at the temperature of the interior of the body, Professor LANG prescribes it in combination with sugar of milk, which easily dissolves in the gastro-intestinal juices, as an excipient for mercurial and arsenical salts in the treatment of syphilis, as he finds that by this means one may feel certain that the quantity of the drug ingested will be absorbed, as no particles of them can pass through the digestive tract unaltered.

Antipyrine has been very successfully used by F. ARNSTEIN in the treatment of pruritus nervosus, and inveterate pruritus scabiei of rather long duration. He gave it in doses of 15-3 grains (i.e., 1 gramme) at bed-time.

Chloroform in doses of from 8 to 10 drops, three times daily markedly improves all the functions of the stomach. It may therefore be advantageously given in the treatment of dyspepsia and various gastric disturbances—V. G. STADNITZKY.

Antipyrin mandolate, a new preparation obtained as crystals by adding antipyrin to mandelic acid, was tried by BENN in 60 cases of whooping cough in children of various ages. With the exception of two failures, it gave excellent results and shortened the duration of the disease. For infants under 1 year he gave 0.05 to 0.10, and for children between 3 and 5 years 0.25 to 0.50 *grm.* No unpleasant nor untoward symptoms were noted.

Morphine, which as a rule, is a slow-acting poison if injected hypodermically into the muscles, will be excreted into the stomach by osmosis, which rules that more morphine will be excreted if it be decomposed as soon as it passes into the stomach. Here then comes the value of *permanganate of potassium* which, though a poison subcutaneously, may be given by the stomach with perfect safety in 1 per cent. solution, whose action is not interfered with by food-stuffs or acetic acid, and if given while morphine is in the stomach, it is an efficient antidote, which completely decomposes grain for grain the morphine.

See air, according to the observations of LINDEMANN, permanently reduces the skin-temperature, and by virtue of its mechanical mixture with salt, acts as a powerful stimulant, whose effect is most marked in persons accustomed to town or country air. The circulation improves, shewing a slower pulse with higher and steeper curves and occasioning longer and deeper inspirations.

Electricity directed by discharge of the electrostatic brush on to the face of a person placed in a properly insulated position, gave LANGE immense satisfaction in the treatment of obstinate migraines that defied all other modes of treatment.

Correspondence.

DR. CROMBIE ON QUARTAN AGUE.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—Will you kindly allow me space for a few words in defence of my letter on "DR. CROMBIE ON Quartan Ague" against the attack made by Babu AMRITO LAL MANDAL in your issue of the 16th March?

Babu AMRITO says: "I was also for sometime at Dinajpur, &c., &c. Out of not less than 750 ague cases which came under my treatment, none gave a history of quartan ague." I think Babu AMRITO knows Dr. PURNA CHANDRA SEN of Dinajpur, who for the last twenty years has been in charge of the Dinajpur Sadar Dispensary, and than whom a more experienced man cannot be found in Dinajpur. He told me the other day that every year fully 50 cases of quartan ague come under his treatment in the dispensary; and during his twenty years' service in Dinajpur, he has treated at least 1,000 cases of quartan ague.

I wrote in my letter, "they get the paroxysm every third day, the interval being seventy-two hours." This is Dr. ROBERTS' definition of quartan ague, which Babu AMRITO does not seem to understand. According to Dr. ROBERTS the paroxysm of quartan ague takes place on every third day and not on every fourth day as AMRITO Babu says. He further asserts that the interval of quartan ague is "two clear days," which is equivalent to forty-eight hours; but according to Dr. ROBERTS, the interval of quartan ague is seventy-two hours. My friend should know that interval means the whole period between the two paroxysms, and includes (but does not exclude) the fever-period. In quartan ague, the paroxysm appears on the seventy-second hour, consequently, according to Dr. ROBERTS it is on the third day, had the paroxysm appeared on the seventy-third hour, then it would have been on the fourth day. Most emphatically, I again assert, without fear of contradiction, that here at Raiganj, quartan ague is very common. I admit that generally, in order of frequency it takes the last place, but it is not so rare in this country as Dr. CROMBIE thinks it to be. There is a village near Raiganj named Elinga where quartan ague is so common, that I think there it takes the first place in order of frequency.

In conclusion, I regret that I cannot follow the advice of my professional brother by giving up my idea of quartan ague. He may think that I am wrong, but I must sincerely and firmly believe that I am right.

I regret the tone of AMRITO Babu's letter, and I advise him, as a friend, to be more moderate and polite in his expressions in future.

Yours, &c., HARA KALI SEN, V.L.M.S.
RAIGANJ, 21st March 1895.

II.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—In the *Indian Medical Record* of the 16th ultimo, BABU AMRITO LAL MANDAL has taken BABU HARA KALI SEN to task for his differing in opinion from himself and Dr. CROMBIE "with regard to certain points in connection with quartan ague." From his experience in the Dinajpur District where he failed to come across any cases of quartan ague, he boldly defends a sweeping

statement that "quartan type of intermittent fever is very rare in India." This kind of generalization is, in the very face of it, neither fair nor logical. Has BABU MANDAL any experience of the existing state of things in the Punjab? If not, I would ask him to make a sojourn in the villages of this part of the Punjab during the cold weather, and he will be perfectly convinced of the truth of the statements I am going to make for his edification. Intermittent fevers of the quartan type were not much heard of ten or twelve years ago in this province, but MANDAL Baba will be able to form some idea of the alarming extent to which this quartan ague has been prevalent here during this decade, from the simple fact that I have treated from 4,000 to 5,000 cases per annum at the medical hall of Messrs. RAJKISSEN MOOKERJI & Co., Chemists, Umballa, for the past 12 years. A simple calculation will show that the total number of cases treated, ranged from 48,000 to 60,000 during a period of twelve years. A little enquiry will further satisfy BABU MANDAL that similar numbers were treated in each of the various medical halls in Delhi, Meerut, Saharnipore, Ludhiana, Umritsar &c., not to speak of the very large numbers who flock to the charitable hospitals, and many others treated by native *hakims* and *vaides*, and many treated gratis by private individuals. I should not omit to mention that this quartan ague is most prevalent during the cold weather, when it rages in an epidemic form in the villages of the Punjab, and many persons succumbed to this fever in the interior of the province, where medical aid was not procurable. As for the quartan type of the fever, BABU MANDAL should rest assured that it is no other. The paroxysms recur on the fourth day after perfect intermission of two clear days during the interval. The villagers have an uncommon dread of this quartan ague, which, according to their nomenclature, is styled "chauthia" or the fourth and sometimes "burra bukhar" or the great fever. I have seen a few instances where the simple villagers, in the absence of any other medicine, had recourse to opium with success in preventing an attack. With due deference to the professional attainments of DR. CHOMBE, I beg to suggest that the state of affairs in the Punjab has not probably come within his cognizance.

Yours, &c., BHAGAT RAM,

Hospital Assistant, in charge of
the Royal Medical Hall.

UMBALLA, 20th March 1895.

III.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—In your issue of the 16th March last, I am deeply sorry to read the cutting remarks made by BABU AMRITA LALL MANDAL of Jalpaiguri in reference to what is stated by BABU HARA KALI SEN of Raigunj in the issue of the 16th January. DR. AMRITA LALL seems to belong to the class of men who are very fond of following the footsteps of others. He does not like to exercise his own independent views and experiences regarding a medical question. He seems to have been horrified to observe that a V. L. M. S. has contradicted a statement made by an M. D., a member of the Indian Medical Service, and certainly a great authority on medical sciences. DR. HARA KALI has simply stated what he has seen with his own eyes, and this is certainly not making a "mountain out of a molehill."

DR. SEN has clearly stated that his patients get the paroxysm every third day at an interval of 72 hours. I must say this is quite correct, if DR. AMRITA LALL will kindly accept ROBERTS' "Practice of Medicine" as an authority on the matter.

DR. MANDAL asserts that he could not find a single case of quartan ague among the 750 patients that came under his treatment. It was, most likely, because he did not classify the cases as to whether they got the paroxysms every day, every other day, or every third day.

In conclusion, it seems to me that Civil Hospital Assistant BABU AMRITA LALL MANDAL and V. L. M. S. BABU HARA KALI SEN are both men of equal qualifications; hence if one derides the designation of the other, he derides himself.

Yours, &c., RATI KANTA MOZENDAR,
Medical Practitioner.

CHAURHAURI DISPENSARY, JAGATI P. O., 18th March 1895.

[In order to settle once for all this controversy on "Quartan Ague," and for the information and satisfaction of both dispensers, we append the following official definition of "quartan ague" as taken from the latest (11th) edition of HOBLYN and PRICE'S Dictionary of "Medical Terms":—

"QUARTAN AGUE.—A species of intermittent fever, in which the intermission is generally about 72 hours, the paroxysms commencing in the afternoon; the usual duration being under 5 hours. The varieties as given by MAISON GOOD, are:—

1. The double quartan, in which the paroxysms of the one set occur in the intermissions of the other, evincing a difference of duration or of violence, with an interval on the 3rd day only.
2. The triple quartan, consisting of a single quartan with regularly recurring paroxysms, while each of the intervening days is marked with a slighter or separate attack.
3. The duplicate quartan, consisting of a single quartan, with two paroxysms on the regular day of attack, the intervals being of ordinary length.
4. The quartan, consisting of a single quartan with three paroxysms on the regular day of attack, the intervals being undisturbed, (i.e., 72 hours).—ED., J. M. K.]

—:O:—

DISINFECTION AND SMALL-POX.

TO THE EDITOR "INDIAN MEDICAL RECORD."

SIR,—Small-pox is associated with such horrors by those who know nothing about it, that its advent is a signal for wholesale desertion by friends, acquaintances and debtors, but not creditors! Accepting without assent or dissent, its general hypothesis of contagiousness, I would naturally ask how, with so eminent a sanitarian and analytical chemist as DR. W. J. SIMPSON at its head, the Calcutta Health Department should relegate the important work of disinfection to illiterate *dhangaris*, and employ in conjunction with each other, disinfectants that, while powerfully acting by themselves, vitiate and utterly destroy each other when combined. S. P. favored me with its unwelcome visit, and in due rote, municipal disinfection was thus effected:—A man came armed with a *belli* (metal bucket) containing carbolic powder, 1 oz of roll sulphur, a broken-necked phenyle bottle and a phial of bichloride solution. The doors and windows (except one) of the infected room having been closed, carbolic powder was freely sprinkled over the floor damped by a spluttering of phenyle in aqueous solution; half a dozen syringefuls of bichloride solution were squirted over decantary portions of the walls, and after turning up his nose and repeating the chlorine-generator that I had two days previously "started to work" in that room, the man placed a lighted coal stove on the floor on which he threw a lump of roll sulphur and walked out of the room, leaving the exit door wide open. His work was done (in 1/4 an hour), and

...the powder of sulphurous acid gas, ... of the light of his countenance.

Note the error.—The room was about 50 feet by 14 feet by 25 feet, or 1750 cubic feet capacity, and to disinfect this there was used about 2 lbs. of carbolic powder (i.e., 196 grains of carbolic acid crude, mixed up with lime and powdered earthy rubbish), 1½ ounce phenyle, (containing about 15 per cent. phenic acid) 8 ounces bichloride solution, (representing 78 grains of corrosive sublimate) and sufficient sulphur to generate 200 cubic feet of sulphurous acid gas; but sulphuric acid has a greater affinity for lime and dissolved mercury, and while every chemist knows that sulphate of lime and mercuric sulphate are not true disinfectants, it is equally admitted that carbolic acid and its admixtures have no influence on small-pox virus: Consequently that room was not properly disinfected, and the Municipal energy and material were practically wasted, while in the public interest I felt myself compelled to seal that room up for two whole days during which it was exposed to the slow but sure action of bleaching powder solution placed over a small stove so as to hot-moisten the air which was thus properly exposed to the full action of the liberated chlorine, which is one of the most powerful germicides known, and which process cost me the enormous sum of four annas (about four pence), while it gave fifty times better results than the Municipal method above detailed, (which could not have been executed at a cost of less than 20 annas.)

With this advantage also, that while sulphurous acid attacks and destroys paint-work, &c., and for several hours after use, stinks out the place in which it has been employed, chlorine liberated from bleaching powder gives the room a peculiarly pleasant odor, and does not destroy furniture, &c.

Yours, &c., ROGER G. S. CHEW, M.D., &c.,

Late Analyst to the Corporation of Calcutta.

CALCUTTA, 12th March 1895.

A PRESCRIPTION FOR DYSENTERY.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

Sir,—The prescription for dysentery which Hospital Assistant Sukdeo Das sent you, and which appears in the *Record* of the 1st instant, is not what I am in the habit of prescribing. Would you therefore kindly make a correction in an early issue?

This is what I give, and it always succeeds in the malarial form of the disease:—

| | | |
|--------------------|-----|---------|
| R. Ammon. Chlorid | ... | grs. v. |
| Pulv. Ipecac. Rad. | ... | grs. v. |
| Tinct. Opi | ... | ℥ss—xv. |
| Mucil. gum. ac. | ... | ℥i. |
| Aq. Cinnamon | ... | ad. ℥i. |

Sig: One such every four hours. I also give 5 grs. of quinine morning and evening.

Yours, &c., R. K. TANDAN, M.B., C.M. (Edin).

Medical Officer.

BALESTON, 19th March 1895.

CHOLERA AND QUARANTINE.

DEBATA.

SERGEON-CAPTAIN P. W. O'BRIEN points out a typographical error in his letter in our issue of the 1st March, the occurrence of which we much regret:—

| | | |
|-----------------------|-----------|-----------------------|
| Dr. Lanson | should be | Dr. Lanson |
| Mr. Farnel | " | Mr. Farnel |
| Communicable | " | Water-communicable |
| Case of communication | " | Ease of communication |
| International | " | Internal |

Lastly.—We have omitted to mention that his paper on *Cholera and Quarantine* was contributed to the Indian Medical Congress.

REVIEWS.

THE ELEMENTS OF PATHOLOGICAL HISTOLOGY, with special reference to practical methods. By Dr. Anton Weichselbaum, Professor of Pathological Anatomy, and Director of the Institute of Pathological Anatomy in the University of Vienna. Translated by W. R. DAWSON, M.B. (Dub.) Demonstrator of Pathology in the Royal College of Surgeons, Ireland; Late Medical Travelling Prizeman of the University of Dublin, &c., &c. With illustrations. (Published by LONGMANS, GREEN & Co., London and New York, 1895.) Price £1. 1 net. Pages 456.

This great work is beyond criticism. In its scope, aim, and embodiment it stands unique. We may therefore *ab ovo* dismiss any thought of criticising it. It affords us much pleasure to point out its many excellences. It is a work of well-established reputation in Germany, and Dr. Dawson, in translating it for English readers in so able and masterly a style, has undoubtedly earned the gratitude of the whole English-speaking *mundus medicus*.

Here are given, concisely and briefly, the doctrines of the science and the most practical and approved methods of investigation.

An important addition to the above are *pathogenesis and etiology*, which render this treatise unique; particular regard being also paid to the *diagnostic* value of the methods of investigation discussed, not only for purely pathological, but also for *clinical* purposes. These methods are noted under two heads, *viz.*: (1) *General* methods, (part I) and (2) *Special* methods (parts II and III). Of course, only those methods are described which accomplish their purpose of investigation for the practical study of this science, with the greatest speed and certainty. Only in a few instances have several methods been given together, in order to enable the student to compare results.

References to authorities and literature have been judiciously omitted, and their place has been taken up with suitable illustrations (drawn from actual preparations and therefore true to nature) because "suitably-chosen illustrations produce a clear conception of facts much more quickly and certainly than even the most accurate description." These figures and drawings have been produced free from all diagrammatic representation, and with a fidelity to the actual pathological conditions presented, which is photographic.

There are eight plates introduced in the work, the first one being: beautifully tinted; (after Kien) and the

specimens of the epidermis, taken on erythrasia plaques and the griseo ketow blotch. These photographs are made from actual cover-glass preparations, stained with fuchsin and mounted in Canada balsam, and were all taken in direct sunlight. Their rare excellence must be seen to be appreciated; to say that they are beautiful, etc., falls far short of doing them justice.

The work has been thrown into chapters, the practical portions having been printed in smaller type than the descriptive, in order to facilitate reference. To complete the work, a concise and full description of the pathological histology of the ear has been appended. Altogether, the volume is beautifully got up and wonderfully up to date (especially in the sections devoted to bacteriology). It is sure to take a foremost place among contemporaneous literature on pathological histology, being thoroughly accurate and complete.

A MONOGRAPH ON DISEASES OF THE BREAST, their pathology and treatment. With special reference to cancer. By W. Roger Williams, F.R.C.S., Late Surgeon, Western General Dispensary, and Surgical Registrar, Middlesex Hospital. With 76 figures. Pages 572. (Published by JOHN BALE and SONS, Great Titchfield Street, Oxford Street, London, W.) 1894. Price £ 1-1-0.

This excellent monograph on *Diseases of the Breast* by DR. ROGER WILLIAMS, consists of 572 pages, and is divided into 25 chapters. It is a most exhaustive and comprehensive work on the subject, and one that will well repay perusal. Treating as it does mammary diseases, in all their multitudinous varieties, the volume opens with the origin of Mammary mamme and their phylogeny, then goes on to discuss their morphology, variations from normal structure, (e.g., amazia, athelia, polymastia. "Mamme Erraticæ" &c.) and their hypertrophy. Next in order, the vast subject of NEOPLASMS is taken up, beginning with Cancer, with special reference to the microbe theory. The pathogenesis, morphology, general pathology, varieties and treatment of acinous cancer are all fully discussed (including the so-called villous duct cancer, and cancers of the mammary integument and of the male breast). The next subject treated is *Sarcoma* (fibro and adeno-sarcoma) and finally, the remaining neoplasms such as lipoma, angioma, chondroma, non-malignant and cystic tumours, inflammatory and suppurative diseases, tubercle, syphilis, traumata and neuroses are each taken up and very fully and ably treated each under its separate heading. But little of the *labor limæ* is required to render the work under review perfect.

DR. ROGER WILLIAMS has set himself a very laborious and onerous task, which he has performed in a most able, succinct and scholarly manner. The treatise is printed in large type (illustrative cases being given in small type), and profusely illustrated. The number of authorities to whom reference is made, indicate that the author has spared no pains to bring his monograph thoroughly up-to-date by widely consulting every possible authority on the subject. We would point out one small typographical error on page 40, line 28, where the word "hesitate" is spelled "hesite."

Government Medical Gazette.

GOVERNMENT OF INDIA.

Surgn.-Capt. A. W. T. Most Sparks, M.B., I. M. S. (Beng), is placed temporarily, at disposal of Govt. of Punjab, Surgn. Maj.-Genl. James Clegburn, M.D., is apptd. to be Surgn.-Genl. and Sany. Commr. with the Govt. of India, in succession to Surgn. Maj.-Genl. W. R. Bice, M.D., C.A.I.

Surgn.-Col. D. O'C. Rye, M.D., apptd. to be Inspr.-Genl. of Civil Hosp., Punjab.

DOMESTIC OCCURRENCES.

MARRIAGES.

MACROBIN—HOLLAND.—On the 3rd April, at St. Stephen's Church, Bareilly, by the Rev. R. A. Cumine, Brig-Surg. Lieut. Col. A. A. Macrobin, M.B., Medical Staff, to Jane Catherine, only daughter of the late Philip Holland, Esq., of Swanage Park, Cueshire.

SETON—ARMSTRONG.—On the 16th March, at St. Simon's, Southsea, Surg. Capt. Bruce Gordon Seton, I. M. S., eldest son of the late Lieut. Col. A. R. Seton, R. E., to Elma, daughter of Lieut. Col. F. H. Armstrong, Southsea.

DEATH.

MOSES.—On the 5th April, at 6, Wood Street, of cholera, Owen, the eldest son of Dr. and Mrs. S. O. Moses, aged 2 years and six months.

NOTICES TO CORRESPONDENTS.

A Native Doctor wanted.—DR. McCABE DALLAS of Kumbhir, Cachar, writes as follows:—"Could you advise a good doctor babu—a man with experience, having a knowledge of English and able to read and understand an English prescription, to come here? A man with a certificate from a college, Hindu, the higher the caste the better. Pay Rs. 40, after six months' approved service Rs. 50. The appointment is permanent, except that misbehaviour would cause peremptory dismissal and two months' notice on either side to terminate the contract, but a good, reliable man might look on the berth as one he could hold for years.

The garden for which the man is intended is alongside of my house; it is compact, with a small hospital attached and bazar alongside."

Candidates will be good enough to apply direct to Dr. DALLAS.

J. J. A. (Panchgani).—See *Indian Medical Record*, 16th November 1894, page 307.

J. H. (Lucknow).—The above note answers your query. Certificates will issue shortly.

N. C. (Bakkar).—A practising physician's fee, when called out of town, is fairly reckoned by a charge of Rs. 10 an hour for the whole time that he is away from his work.

H. P. B. (Panchabdra).—The Sanskrit translations of medical works dealing with special subjects tersely and clearly written would, we think, be of great interest. We have your meteorology papers under review, but at present articles of great medical interest command our space. The report of the last snake-bite case will soon be published.

M. A. A. (Hyderabad).—You have been of great service to the Association, and your interest in securing members is much appreciated.

T. H. (Lucknow).—We shall give your matter early attention.

P. V. R. (Bengal).—Candidates for the M.B. degree of the University of Bombay must possess complete British qualifications in medicine, surgery and midwifery, and the examination must be passed in Bombay. For further information refer to the *Medical Register and Directory of the Indian Empire* to be had of this office.

H. K. S. (Raiganj).—Your letter appears in this issue.

J. E. W. (Kimari).—The form of application for membership is given in the Association's advertisement. Send in your name and those of others.

V. C. H. M. (Manamalkudi).—Apply to the Manager, *Medical Times and Hospital Gazette*, 11, Adam Street, Strand, London.

D. D. (Rajkote).—Your paper will appear in an early issue.

E. A. (Myitkyina).—The memorial of the Indian Medical Association is, we learn, receiving kindly attention at Simla.

W. D. W. (Solangore).—We shall be glad to help forward the movement of the Assistant Surgeon of your settlements. Please give us full particulars and refer to back numbers of this Journal for information and guidance.

C. A. R. H. (Dagehui).—Refer to Vol. VII, page 169, also to our Current Medical Literature section, July 1894.

THE TREATMENT OF THE BITES OF RABID ANIMALS BY PERMANGANATE OF POTASH.

By D. MORISON, M.D., C.M.
Rampur Boalia.

WHAT treatment should be adopted for the bites of rabid animals, so as to give the patient the best chance of escaping hydrophobia, is a question of absorbing interest and importance at the present time. It is at all times and in every country important to the surgeon, but especially so in India, where deaths from hydrophobia, if they were correctly reported and registered, would show a high and widespread mortality. In the following record of cases treated by permanganate of potash, I trust there is some approach to answering that question:—

During the last seventeen years I have had so many cases of bites of rabid animals—jackals and dogs—and such uniform success in their treatment, that I deem it worthy to lay the facts before the medical profession.

CASE I. *Dog-bite*.—As far back as 1879, I had my first case of rabid dog-bite. A little girl, aged ten years, a Mohammedan, was brought to me twenty-four hours after being bitten, from a neighbouring village suffering from extensive laceration of the scalp. I learned from her mother, who accompanied her, that her daughter was playing near her, when a strange dog, which she believed was mad, attacked the child, knocked her down, bit her forehead, tearing her scalp. The dog was driven off, and was seen immediately after attacking a dog belonging to the village. I had, previous to this in the end of 1878, begun to use a weak *permanganate of potash* solution as a dressing for simple ulcers and sores—a cheap and efficient dressing—to replace carbolic oil and carbolic solution, which I found inefficient for patients who had to walk miles in a scorching sun or work all day in the fields. The *permanganate solution* could be given each patient in such quantity that he could, without opening his bandages, keep the dressing *continuously moist*, making it impervious to air, and keeping it practically antiseptic during day and night. It occurred to me in this my first case that, as the *permanganate of potash* was such a powerful oxidising agent, parting readily with some of its oxygen to organic substances, it would at least be as rational a mode of treatment for bites of rabid animals as any other treatment then known to me. I therefore washed the lacerated scalp with a strong solution of *permanganate of potash*—(I did not then note the exact strength; but it would have been probably 8 to 10 grains to the ounce of water. I now use 8 grains to the ounce on the first application and keep the wound dressed with 3 grains to the ounce),—bandaged the head, giving the mother a solution of 8 grains to the ounce with instructions to keep the dressing *continuously moist*, day and night, as far as possible. The wounds healed kindly and the child was well in three weeks. Before the child's wounds had been quite healed, the village dog which had been

bitten, became rabid, and the mother of the child came to me in great alarm, as the villagers assured her that her child would also go mad. I tried to infuse hope into her, although I was not over-hopeful myself. The child was alive 5 years after.

CASE II. *Dog-bite*.—I determined to follow up this line of treatment in the next case that came to me. In the beginning of 1880 a Mohammedan lad, aged 17 years, was brought to me by his father, 24 hours after he had been bitten. The lad was saying his prayers at midday on the banks of a tank near his father's house, when a rabid dog attacked him from behind, biting him severely on the leg. He at once tried to beat off the animal with his hands and feet, but to no purpose, until he seized it by the throat with both hands and strangled it. The lad was so severely bitten, and in so many places, that it required time and great care to open out every wound and scratch, and apply the *permanganate solution*. He came daily to be dressed and made a good recovery, notwithstanding the evil prognostications of his friends. He was alive and in good health three years after.

CASES III and IV.—My next two cases were to me cases of great anxiety. I had a little pup, not a year old, which had been bitten by an undoubtedly rabid pariah dog. I shot the pariah dog, but kept the pup, to see if he would become rabid, and if so, how long after being bitten. I kept him tied up and fed him as usual, my servants being warned not to go too near him. On the 14th day after the pup was bitten, as two of my servants were passing by within range of him, he snapped at them, biting both in quick succession. It was only then my attention was drawn to him, and I found him salivating freely, snapping at the air, biting his hind legs and the rope with which he was tied. I had him shot at once. The first man bitten was my bearer or personal house-servant—a native Christian. He was bitten on the big toe, and the wound was a deep incised one, apparently made by the incisor teeth, which were very sharp in a pup so young. The second man bitten was my syce, or groom, a Hindoo; he was bitten on the right leg over the anterior lower third of the tibia. The wounds were attended to immediately, and carefully opened up, washed with *permanganate solution*, and dressed as the previous cases. The wounds healed quickly, and I had them both under observation for two and three years respectively in perfect health.

CASE V.—This case was a *chuprassie* or messenger, a Hindoo. He had gone out to a field in the early morning, according to native custom, and when in the act of defecation, was attacked by a mad jackal and bitten in the right leg over the tibia. He came to me about six hours after he was bitten, and was treated and dressed in a similar manner to the previous cases. He was under observation for eighteen months in perfect health.

CASE VI.—This case was a jackal-bite. The patient was a Hindoo, an old man 60 years of age, watchman at a Government godown or store-shed. He was attacked on the main road, in the early morning, and bitten on the leg. I saw him a few hours after he was bitten. He made a good recovery, and was well for one year, after which I lost sight of him.

CASE VII.—A Hindoo musician, in a village not far from my dispensary, came to me in a state of great

*A paper read before the Indian Medical Congress and sent to the Record for publication.

hysterical, with his leg covered with blood. He had been sitting in the sun's rays, warming himself in the morning, when a mad jackal rushed at him and bit him in the leg. He was very nervous and apprehensive of hydrophobia. He was treated as the others, and was well two years after being bitten.

CASE VIII, IX, X, XI.—Here we have four cases which I may group together. In a village a few hundred yards from my house, a mad jackal attacked a goat tethered near one of the huts. The grandmother of the house came to rescue the goat, the jackal turned on her and bit her; the daughter-in-law came to her aid, and she also was bitten; a neighbor, a young man, came to drive the jackal away, and he too was bitten. The jackal then disappeared into the jungle behind the village. The son of the old woman, the first victim, came home from the field shortly after, and finding his mother and wife bitten, armed himself with a bamboo and went in search of the jackal. He had only gone a few yards from the village when he saw the jackal coming towards the village again. He tried to strike it, but missed his blow; the infuriated animal rushed upon him and before he had time to defend himself he was bitten on the leg. These four were patients of mine, and received the same treatment. All were in good health eighteen months after.

CASE XII.—A Mohammedan ryot, who lived 10 miles from my dispensary. I saw him two days after he had been bitten by a jackal, supposed to be mad. His wounds chiefly on the legs were crusted over. I opened each one and applied the *permanganate solution* as in previous cases. He did well, and I never heard of his illness or death, although I frequently enquired about him from villagers who came from his village.

CASE XIII.—This man was a boatman on the Ganges. He was attacked by a rabid jackal on the highway; was treated as the previous cases, and did well. He was under observation for three months, after which I lost sight of him.

CASE XIV.—A Mohammedan ryot, bitten by a rabid dog. I saw him 24 hours after he was bitten. I treated him as the others and had him under observation for about a year.

CASE XV.—This was a case seen on tour in the interior of the district, at a distant village. He was bitten by a rabid jackal, and was similarly treated. He was well six months after, by the reports of friends who knew him.

CASES XVI, XVII.—These two cases were two brothers, sons of a Hindoo carponter, who was in my employ at the time the incident occurred.

The first (Case XVI) a boy eight or nine years of age, was attacked by a rabid dog which entered the courtyard of the house. The elder brother, a lad of 18 or 20 years, seeing the animal attacking his brother endeavoured to drive it off. The dog seized him by the hand and would not let go its grip until assistance came, and the animal's mouth was forced open with a bamboo. Both were brought to me by their father on the following morning 18 or 20 hours after being bitten. Case XVI had an abrasion on the chest and leg quite superficial and easily washed and dressed. Case XVII, the elder lad, had a deep punctured wound on the ball of the thumb (palmar aspect), and a superficial incised wound on the dorsal

aspect. I proceeded to open up the wound, after applying the *permanganate solution*. When the father, seeing the pain his son was put to, intervened, and he withdrew his hand, and would not permit me to proceed. I then offered to give him chloroform, but he refused, and I was obliged to let him go with a superficial application of the solution, which I feared would be of no avail. I explained to the father the grave risk he was incurring; but they seemed to prefer trusting to fate than to undergo the operation. The elder lad (Case XVII) died of hydrophobia 21 days after the bite. The younger was alive and well four years after. I shall always regret that I had not first put him under chloroform, which he might have submitted to, before he felt the pain of the operation.

CASE XVIII.—This was a boy 9 or 10 years of age, a Mohammedan, bitten by a rabid dog in a village near my house. The villagers came running to tell me that a mad dog, which had bitten a boy, was approaching my house. I took my gun, followed the dog to make sure that he was rabid before I shot him. He laid down in the shade of a shrub behind my stables. He was panting, snapping the air, and saliva was dribbling from his mouth. I shot him. The villagers then told me he had bitten a village dog. I sent for the boy who had been bitten, treated him, and he was well four years after. I got possession of the bitten dog, tied him up and had him fed daily. On the eleventh day he became rabid, and died on the fourteenth day.

CASE XIX.—A boy, 7 or 8 years of age, a Mohammedan from a village not far from my house, was brought to me by his father, who said the boy and some other men—how many was not known—were bitten by a rabid jackal. I treated the boy as in previous cases. About 18 or 20 days after two men were brought to me suffering from hydrophobia. I could do little for them, they both died in three days. These two men and the boy were bitten by the same jackal. The boy was alive and well some years after.

CASE XX.—A Mohammedan Monvie was bitten by a rabid dog. He was treated as the other cases. He is still alive, six years after being bitten.

In addition to these twenty cases, I have had about 8 or 9 others, of which no definite record has been kept, as it was found impossible to verify the condition of the animal, or to keep them under observation a sufficiently long time to test the results of treatment.

Analyses of rabid bites.—If we tabulate these cases, we have two columns numbering respectively 9 dog-bites, and 11 jackal-bites.

| Dog-bites. | | | | Jackal-bites. | | | |
|--------------------|-----|---------------------|---|------------------------|----|--------------------------|--|
| Nos. | 1. | Certainly rabid. | 7 | Nos. | 5. | All presumably rabid. | |
| | 2. | | | Certainly | 6. | | |
| | 3. | | | rabid. | 7. | | |
| | 4. | | | | 8. | | |
| | 14. | Doubtful. | 2 | Doubtful. | 9. | | |
| | 16. | Certainly | | 10. | | | |
| | 17. | rabid. | | 11. | | | |
| | 18. | Certainly | | 12. | | | |
| | 19. | rabid. | | 13. | | | |
| | 20. | Doubtful. | | 14. | | | |
| Total 9 dog-bites. | | | | Total 14 jackal-bites. | | | |

Dr. J. M. B. BARNES, who suggested this treatment in 1884, two years after I had begun to use it, says: "It is not to rely on statistics in the treatment of the bites of rabid animals, as they are of 'a most erratic character.' This warning is needed, and that it may not be disregarded, I will endeavour in analysing these cases not to lay greater weight upon them than they legitimately warrant.

If we glance at these cases, we see that they consist of eleven jackal and nine dog-bites. I will consider the jackal-bites first. Every one knows how impossible it is to follow up a reported mad jackal after it has bitten, to ascertain whether it is really rabid or not. It is usually either killed on the spot or it escapes into the jungle, to be seen no more. Here then at the very outset we have an element of considerable uncertainty introduced into these eleven cases of jackal-bites. And yet the uncertain element is not so great as it may at first seem. Those who have lived for any considerable time in outstations in Bengal, know that the jackal is naturally an exceedingly timid animal, in presence of man or animals. I have seen a little English fox terrier chase a pack of jackals and scatter them like sheep. It is rarely, if ever, known to attack a man unless it is rabid. * SIR JOSEPH FAYRER, when writing of two men who were bitten by one jackal, says: "Only a mad jackal would do this, as it is a very timid animal, and never otherwise attacks men."† My experience corroborates the truth of that remark, and would add especially in daylight. All these eleven persons were bitten by jackals in daylight. How many of these jackals were rabid, and in how many instances the virus entered the wounds, are questions to which we can only give approximate answers when we come to deal with statistics of rabid bites.

The nine cases bitten by dogs clearly show that of them seven at least were bitten by rabid dogs. Thus—Cases I, II, III, IV, XVI, XVII, XVIII leave no doubt in our minds that the dogs which bit them were rabid.

We now come to consider the question of statistics, which, although confessedly unreliable and erratic, is the only course left open to us in cases of this kind.

It has been stated by one writer‡ on hydrophobia, that when no preventive measures are adopted, "at least half, perhaps two-thirds, escape." DR. RUFFER stated, before the Society of Arts, London§ that 80 per cent. of those bitten on the face by rabid animals died; and that 15 per cent. is the lowest mortality amongst those bitten on any other part of the body. In July 1885, five boys coming from school in London were bitten by a rabid dog, and all the five were cauterised by skilled surgeons. They all died from hydrophobia within four months. These are statistics based on cases occurring in Europe, where the action of the virus is neither so rapid, nor so certain as it is in India—chiefly on account of the climate, and the scanty clothing of the people. The statistics in India, which DR. VINCENT RICKARDS found so variable, contain the uncertain element of whether the animal was mad or not. It has never been shown

that in India, "one-half or two-thirds" of those bitten by rabid animals escape, when preventive measures are not used. Surgeon J. BALFOUR, for many years in the Bengal Medical Service, referring to a native who had been sent to him by his European master as one of 17 or 18 persons bitten by a rabid animal, says:—"The injuries were on the calf of one leg and dog, but did not bleed much. I put him under chloroform, carefully excised the bitten part, &c. The man was sent home with instructions as to future treatment. Of the 17 or 18 men who were bitten, all died within three months, and this man recovered."¶ I quote this to show the proportion of those who escape in India, when fairly bitten by rabid animals, and no preventive measures are adopted! I am, however, not prepared to accept this instance as a type of what usually occurs; but as regards Bengal, it is nearer the truth than "one-half or two-thirds" escaping. I have found that in most cases the percentage of deaths is very high, when no preventive measures are adopted, usually ranging from 80 to 90 per cent. of those who are really bitten by rabid animals. That the percentage is not higher, I attribute to the habit of the people, when bitten, going to the nearest tank to wash their wounds. I will not, however, in discussing the 20 cases before us, take advantage of the higher percentage mortality in India; but accept the lowest percentage in Europe quoted by DR. RUFFER, viz.—15 per cent. as applicable to the cases we are considering. Even if we allow that one-half of these 20 cases were bitten by non-rabid animals—a far too generous allowance—we have still 10 cases of undoubted rabid bites with only one death—due not to the failure of the treatment, but to the neglect of proper treatment—giving a mortality of 10 per cent. That means, that deaths from rabid bites on the naked limbs in India were 5 per cent. lower than bites on any part of the covered body, except the face, in Europe. This result, so far as I know, has not been equalled by any other kind of treatment, excepting, of course, PASTEUR'S inoculations. But, according to all fair rules of criticism, a case such as No. 17—the one who refused to allow me to open up his wounds—should be left out of the statistics altogether. If we do so, the results, whether we exclude one-half as doubtful or not, are unprecedented. A series of 10 or 19 cases, whichever number we may feel disposed to accept, without a single failure. I am quite well aware, that this series of apparently successful cases does not prove that permanganate of potash is an antidote to the virus of hydrophobia. In 1884, when I submitted my thesis on this subject to the University of Glasgow, embodying the first fifteen cases of this list, I pointed out that only by experimental investigations could the question whether it was an antidote or not to the virus of rabies, be finally settled. I am not aware that such investigations have been undertaken, and until they are undertaken, and an authoritative answer is given to the question, the above record of cases must remain as an incentive to others to adopt the same treatment, until a better is found.

There are two questions—speculative questions as yet, I admit—which force themselves upon my attention as

* Lancet, 11th June 1887.

I thought over the obscure problems of this dreadful disease.

1. What is the nature of this subtle virus?

2. How does the permanganate render the virus innocuous, if it proved to be an antidote to rabid virus?

The nature of this virus, which has hitherto eluded detection, defying the efforts of our most eminent chemical and bacteriological investigators, is at present wrapped in mere conjecture. It would be difficult in such a well-trodden path to strike out any new path, or theory even; but if old theories are confirmed, it were not amiss even to reaffirm them. Hitherto the microscopic investigations, although often hopeful, have not yet been able to discover any micro-organism invariably associated with the disease; nor any organism which on being cultivated in suitable media, can produce the virus of rabies. It seems to me highly probable, from noticing the characteristic behaviour of the virus, that it is a ptomaine produced by some lowly organism, with a life history not very dissimilar to that of the bacillus of anthrax. Although these two diseases—anthrax and rabies—are by no means similar, yet there are some features in which these two diseases resemble one another. This will be seen from the following five characteristics which apply to both:—

Anthrax.

1. A disease of herbivora communicable to men and animals.
2. Has a varying period of incubation from 4 to 9 days.
3. Communicated by inoculation.
4. Virus remains at seat of inoculation for some hours or days before affecting the system generally and causing death.
5. May be prevented by excision and destruction of point of inoculation.

Rabies.

1. A disease of carnivora communicable to men and animals.
2. Has a varying period of incubation from 8 to 90 days.
3. Communicated by inoculation.
4. Virus remains at seat of inoculation for hours or days before affecting the system generally and causing death.
5. May be prevented by excision and destruction of point of inoculation.

The resemblance would be still more striking if the virus of these two diseases could be rendered innocuous by bringing them into contact with a solution of the permanganate of potash, of a given strength. Not only so, but the attenuation of the virus could be controlled up to any point, with the certainty of a chemical equation, should this prove true.

We know how the virus of anthrax is attenuated to form a vaccine, which effectually protects animals from the disease; and how by exposure to dry air the virus of rabies has been attenuated presumably by the oxygen of the air. A similar attenuation has been obtained by heating the virus in vacuo; but the attenuation thus obtained is said not to be permanent. The attenuation produced by compressed oxygen remains permanent. PASTEUR has pointed out a most important distinction in the process of attenuation of the virus of rabies which takes place when it is brought into contact with dry air. It "is an effect of a diminution of the quantity of the virus of rabies contained in the spinal cord, and not an effect of a diminution of its virulence." This fact lends support to the

efficacy which I claim for the permanganate of potash as an oxidising agent brought into actual contact with the virus of rabies in wounds, caused by the bites of rabid animals. From these facts it seems highly probable that oxygen, whether in the form of dry air, compressed oxygen, or by chemical action as with the permanganate solution when brought into contact with the virus of rabies, destroys the virus and renders it innocuous. The treatment, therefore, which I have adopted and recommend to others, is in accordance with the most recent advance in bacteriological science, and promises to become an important and permanent ally to the treatment by inoculations with attenuated virus—a treatment which we can never hope to see made available to the ordinary Bengal ryot. The permanganate treatment on the contrary could be placed in the hands of the ordinary ryot or peasant with a few simple instructions; and, in slight superficial wounds—which are as dangerous as deep ones—he might effectually ward off hydrophobia in a great number of cases.

—:—:—

PLASMODIUM MALARIE, ITS IMPORTANCE IN THE DIAGNOSIS OF TROPICAL DISEASES.

By SURGEON-CAPTAIN PATRICK HEHR, M.D., F.R.S.E.,

F.R.C.S.E., D.P.H., (Cantab).

Bengal Medical Service; Lecturer on Pathology and Medicine, His Highness the Nizam's Medical School.

We have used the microscope for diagnostic purposes in doubtful pyrexial states for the last five years, and although the results cannot always be relied upon, we conclude that whenever free crescents, spherules, red blood cells containing hyaline bodies increasing in size, flagellæ or flagellulæ are present, the patient is suffering from some form of malarial poisoning.

After the manner of GOLGI, an attempt was made to connect the development of the organism with the different stages of ague, but in this respect very little beyond what has already been ascertained by that distinguished investigator could be brought out.

Cases were examined just before, during and after the paroxysms. The following remarks represent what was found in several cases of quotidian ague, all of an acute type:—

During fever the spores, both free and within the red blood corpuscles, were always seen, and always associated with free amoeboid bodies. Spherical cells, especially the "simple" kind, were invariably present, but in some instances they had attained a later stage of their development—flagellate processes being seen projecting from the surface. The larger varieties of the free parasite were sometimes found. It was repeatedly noticed that at the end of three or four hours, the number of red blood cells infected by spores appeared to be considerably increased.

It is remarkable that no relation could be established between the different forms of the parasite and the varieties of fever. It is likewise striking that in three cases of slight fever, large numbers of the immature varieties of the parasite were found; in the first the temperature was 99.8° Fahr., and the patient had only suffered from two

in the other two the temperature was not beyond 101° , and usually not beyond 100.5° , and yet the parasites were always in abundance even during apyrexia.

About six weeks ago, we had the good fortune to meet with a case of chronic malarial poisoning in which tertian ague was still recurring. In this case every form of parasitic growth yet discovered was visible. It is in these cases of chronic malarial poisoning, especially when the ague continues, that the polymorphism of the plasmodium malarie is characteristically met with, and they are then as a rule, in considerable numbers.

We might here say that those not yet familiar with the subject should apply the microscope to the diagnosis of malarial diseases, but we would remind them that some inexperienced observers have undoubtedly taken certain natural constituents of the blood, and the products of blood-coagulation for the various forms of the parasite.

We can only mistake the parasite for one or other of many of the constituents of healthy or morbid blood, and what these constituents are, need not be here enumerated. Nor need we now state how the various forms of the parasite are to be differentiated, but we should always be cautious as regards "vacuoles" in red blood-cells and the "blood plates" of HAYEM.

It has been established, as a rule, with many exceptions, that the severity of the attack is in proportion to the number of the parasites in the blood. This may be made a matter of daily observation in areas of endemic malaria. There are, as stated, many exceptions, where patients, for instance, suffering from severe fever, possess few microbes and less frequently, where with many, the attacks are mild.

We need not go into detail regarding those assertions which were made a few years ago, according to which, in the most diverse infectious diseases and cachexie, "similar bodies" to LAVERAN'S parasite had been found. It is through such errors that the pathogenic and etiologic importance of LAVERAN'S malarial parasite was depreciated, but now most of the authors of such statements have admitted that they erroneously mistook other things for parasites which were not so, or *vice versa*.

Similarly, we might differentiate all normal constituents from parasitic structures, but this is not here necessary.

The following highly interesting table, modified from one of the most recent works on bacteriology, gives at a glance the chief general and special characteristics of the *plasmodium malarie*. There are several points in the table with which we do not quite agree, but in the main the table expresses the views of the best authorities on the subject.

Place found.—In blood corpuscles of those suffering from malarial poisoning.

Form and Arrangement.—Protoplasmic corpuscles of varied form (round, oval, crescentic bodies and flagello), with or without pigment, as the malarial process in which they occur is chronic or acute, due to changes occurring in the hæmoglobin. They present a cortical substance (ectoplasm), surrounding a less colored portion (endoplasm), which contains sometimes one or more dendri and senescent.

Motility.—Rapid amoeboid movements.

Growth.—A method by which these organisms may be cultivated outside the human body has not as yet been found. They probably need a vital nutritive medium.

Spore-formation.—It multiplies by cleavage of a whole or part of the protoplasmic substance. It becomes stationary, and the pigment of those so supplied, accumulates in the centre, while new elements bud from the periphery, which elements may from the first be pigmented, and may possess undulating flagella.

Active reaction.—The organisms may be observed when the blood is fresh. A strong lens is required. ~~Zinn~~ $\frac{1}{2}$ to $\frac{1}{4}$ immersion lens, apochromatic preferably, to detect them. Dry preparations may be beautifully stained by methylene blue. These high powers are not, however, absolutely indispensable. It is well known that their discoverer first saw this parasite with a dry objective lens, having a magnificate of $\frac{1}{4}$ only.

Pathogenesis.—The blood of a person suffering from malarial disease inoculated into the blood of a second individual, produces a typical malarial attack, and the organisms multiply and are capable of producing progressive infection. They disappear rapidly under the administration of quinine.

CELLI and GUARRETI believe that the organism belongs to the genus *sporozoa* (*protozoa*), family GREGARINIDÆ and order COCCIDIUM.

The diagnostic relations of the malarial parasite are highly important, but at the threshold of this subject we are beset with many difficulties arising out of the extremely complex nature of the phenomena associated with malarial poisoning, and from the absence of any definite evidence as to the relation of any particular form or forms of the organism with special clinical manifestations of malarial infection, the polymorphic nature of the parasite itself adding its share to the intricacy of the points under consideration.

It should be observed that there are still many competent observers who have not accepted the malarial plasmodium as the sole cause of paludal fever, and the whole subject is so new, that even those who accept Laveran's views find it impossible as yet fully to explain all the different clinical phenomena on this theory without some reserve. It appears certain to us however, that the germs exist in human blood during and between malarial paroxysms in numbers sufficient to exert powerful effects; for they can often be found in almost every drop of blood drawn. Moreover, the parasite is never discoverable in normal blood, or in diseases other than such as arise from malarial poisoning. In chronic forms of ague, in doubtful cases, the presence of the germ in the blood is of great value in diagnosis.

The hæmatozoa live at the expense of the normal elements of the blood. The invaded red blood corpuscles grow paler and paler in proportion to the development of the parasites, and even the colors of the colored cells at last disappear. It may be said that no anemia, except the anemia resulting from hæmorrhage, can be better explained than paludal anemia.

Moreover, anemia is the most constant symptom of paludism. All authors who have described paludal

phenomena, have insisted on the rapidity with which anaplasma takes place. A few grave attacks of ague are sufficient to make a patient unrecognisable, so marked does the anaplasma become. But curiously enough, certain patients become anæmic and fall into cachexia without having any fever. Anæmia constitutes with them the principal, and so to speak, solitary symptom of the infection.

The early diagnosis of remittent from enteric fever is sometimes an exceedingly difficult matter, not in their typical forms, but in those cases where there are such departures from the usual conditions as to lead us to doubt the nature of the case. We have seen physicians in India of wide experience and high repute, hesitate before giving a definite diagnosis earlier than the seventh or eighth day. On two occasions we have been able to confirm a provisional diagnosis of remittent fever by finding the malarial parasite in the blood in both cases, although they had both been pronounced to be enteric.

In the early stage of a pure remittent, the malarial parasite is to be found, in that of enteric it is not. All physicians will at once appreciate the value of this point.

In that complicated affection known as "typho-malarial fever," although the significance of the existence of the malarial parasite in the blood is less manifest, still it may be important to know as a guide to therapeutics, that malaria has its share in the symptoms. It would be very interesting to be able to confirm or refute the statement of LAFERAN to the effect that when in this disease, the enteric symptoms supervene, the malarial organisms disappear, and that they reappear, should the patient get ague subsequently. We have not met with a case of typho-malarial fever during the last two years to test this point.

In our brochure on the subject published three years ago, we showed that the occurrence of hæmoglobinuria in malarial infection was related to malarial parasites. We had not then, however, as we have now, proved that more or less hæmoglobin is to be found in the urine of all (or almost all) malarial fever patients, certainly in all cases of severe malarial fever and malarial cachexia.

Our attention was first rivetted to this subject in the year 1899, when we were treating three out of five members of a family that acquired malarial fever of a severe remittent form, all of whom had hæmoglobinuria. In none could a single red corpuscle be discovered in the urine. The patients were related as daughter, mother and grand-mother.

Allowing that toxins are produced in severe malarial infection, it is not improbable that these poisonous products of disintegration of the malarial parasite acting upon the cerebral grey cells, help in causing the symptoms just in the same way as other pyrogenetic bodies excite thermogenesis.

The varying effect or intensity of the *materies morbi* of malaria is well known. In such cases we have to fall back upon the theory of individual peculiarity, which might consist in a heightened irritability of the nervous system, or in some unusual chemical composition of the blood, which offers to the parasite (in the severe cases), a soil adapted to the production of particular poisonous bodies. Again, a difference in the toxicity of the parasites should be recollected. The co-existence of such factors

in malarial infection is shown from the diversity of the course of the disease under apparently similar circumstances. Thus, of several persons exposed to the action of malaria, some will get malarial fever, or other malarial diseases, whilst some will not. Of those afflicted with fever, some will get it acute, others late, or some severe, others mild; in some a cure will arise spontaneously in a few days, in others, after a week or so, whilst others go from bad to worse till they suffer from malarial cachexia.

The mass of evidence of a positive nature, collected by some of the best bacteriologists living, and in the shape of large numbers of cases, should make us especially careful of diagnosing malarial fever or malarial disease in general, in the absence of the organism from the blood. Again, we should bear in mind that against an exceedingly small number of negative results, there is a large number of positive, indeed, there are many reasons for believing that if the blood from internal organs was examined, and not that of the periphery, the number of negative cases would be much reduced.

Many now believe that a poison may be present in the spore-forming bodies, which give rise to the paroxysm by affecting certain nerve centres. The evidence of recent research in connection with toxins would tend to support this; and the fact that after a paroxysm of malarial fever, poisonous bodies are eliminated by different channels, gives very great probability to it. It has been proved that the urine passed immediately after an attack acts as a potent poison to rabbits, whilst that passed some time after, or before, or during a paroxysm, is much less so; the sweat of malarial patients kills the same animals, whereas normal sweat does not. It is suggested by MANNING that the poison produced by the parasite is like that created by the streptococci of acute suppurations; the clinical pictures of malaria and ordinary surgical sepsis also resemble one another, which appears to justify the idea that there is a relationship between the agent causing the illness in both diseases—the one is a fungus-sepsis, and the other a malarial or sporozoon-sepsis.

Changes of type of fever are now capable of easy explanation. Long before GOLGI's observations were made known to English readers, we had conducted and published the results of certain investigations which showed that the explanation lay in one or more generations of the parasite carrying on their existence in the blood simultaneously or from one or more generations ceasing to multiply, or undergoing disintegration.

Postponings and anticipations of paroxysms may also be readily explained by slower or more rapid development of the organisms; and exaggerations of these states or the falling out of one generation where there are two or more, may also explain changes of type, such as the alteration of a double quartan to a single quartan, or of a double quotidian to a single. Hence the curative effects of quinine, and also the prophylactic use of quinine in malarial places, and the necessity of beginning the use of the drug some days before exposure to the malarial influence.

My own observations show that in malarious localities the parasite is constant in those not taking quinine, constant even in health, but they are then present in large numbers. It is quite possible that there may be influences at work

to the human body, keeping it within bounds, and that malarial manifestations arise only when these influences are, for some season, out of order. Many years ago, we remember reading the view entertained by some authority (Dr. Bangs-Jones, we think) to the effect, that malarial fevers in tropical climates were due to the temporary absence from the blood of an organic body which he designated "animal quinine," and that the place of this agent could be adequately taken by "vegetable quinine," and lastly that this explained the virtue and curative influence of quinine in such diseases.

These parasitic micro-organisms of malarial infection have been found only in malarial diseases, and they have been constantly found. Malarial paroxysms have been produced in a healthy person by inoculation of blood containing such organisms. They disappear under the use of quinine.

Experiments shew that after febrile paroxysms the hæmatozoa disappear in part from the general circulation.

It may be premature to express a definite opinion in this connection, but there are a number of facts that go to shew inferentially, that it is the *fons et origo malorum*. Its existence in malarial conditions offers an easy explanation as to the cause of the cachexia and localised pigmentations produced. The destructive effect of some agent on the red blood-cells is as a matter of fact, one of actual observation.

The period taken for the development of new bodies corresponds to the intervals between the paroxysms (Golds). The constancy of the organism in ague and remittent fever, the power of quinine to cure the disease, the effects of irrigation with quinine solutions on the organism, and lastly, the fact that dogs into whom malarial blood was transfused, got the disease (the organism not being present in the dog's blood before the transfusion), shew the relation between the parasite and ague, and again between it and remittent fever.

DOCTORS AND THEIR PRESCRIPTIONS.

By WM. HUNTLY, M.A., M.D.,

Kotah.

A SHORT time ago, in the medicine bill of a London hospital, my eye caught the name "bismuth" and after it the sum £25, the amount paid for bismuth alone during the previous year. The sum to me was large, and all the more so, since bismuth is a drug which I but seldom prescribe in India.

The consumption of a large amount of bismuth in a London dispensary means, I should say, a large number of patients suffering from a form of indigestion which prevails more in large centres of population; but I think that it means more than this. There is a terribly long list of medicines, now-a-days, to choose from, and as I read over a new therapeutic index sent me, I could not but pity the position of the coming medical student.

The doctor in practice having no examination resting on his mind looks at such a list in a critical way, scans it, weighs the evidence for and against the drug, and mentally rejects or approves. Those approved are tested in practice and then independently of all other evidence, are finally added to or cut off from his prescriptions. One

doctor thus meets another, to find that their prescriptions for certain diseases are totally different, and yet, with justice, they both point to good results from their different lines of treatment.

Some doctors having perhaps retentive memories, hold to a great variety of prescriptions, while others earning an equal reputation, pin their faith to a few. There is the man who has forty drugs for one disease and the man who has one drug for forty diseases. The story goes of a famous old doctor who worked a large out-door practice with two huge bottles, one filled with a cough mixture, and the other filled with a rhubarb mixture, which he used for constipation and diarrhoea indiscriminately. Questioned how he could treat two opposites with the same rhubarb mixture, he philosophically replied that in the one case relief of the loaded bowel was obtained, and in the other the irritating material was carried off!

There is no doubt that the theory held by the physician with regard to a disease, influences his choice of drugs. Take, for example, malarial fever. One man holds that the root of the matter lies in the intestine, and if a flux free enough to carry off the factory whence issues the malarial germ, the poison present in the blood will die out of itself.

Another man places the importance on the liver and its derangements in connection with malaria; he holds that the battle is to be fought out with the liver as the fort from which the enemy carries on operations. In such a man's prescriptions calomel occupies a prominent place. Still another lays stress on the nervous factor and dispenses accordingly.

Yet, again, in malarial fever, the questions of the amount, frequency of dose, and time of administration of the quinine compounds are not settled to the satisfaction of all. Even quinine itself has its few doubters, seeing that occasionally in spite of its administration the fever is not stopped.

A year or two ago, I read of a case of malarial fever (tertiary I think) which resisted all remedies. At last some old nurse recommended that a blister be applied along the spine; the cure was immediate and permanent after the first blister.

Such divergencies in principle and practice are apt to lead to an attitude of scepticism towards medicine in general. I remember an old retired surgeon-major telling me that the only thing he was sure of in medicine was sulphur—for itch!

A correspondent of an American newspaper went the round of a number of doctors and described an imaginary ailment, receiving from each a prescription. These he published, poking fun at the medical profession in general. But scepticism, either in religion or medicine, as a rule, is knocked on the head when trouble comes!

From the many diversities in practice, the conclusion forces itself to the front, that a doctor employs that drug for which he has a predilection, in the manner most beneficial to his patients. His attention has been attracted to a certain drug, it may be by the enthusiasm of a teacher, or by a number of successes brought about by its exhibition. He proceeds to master the various lines in which he can employ it; he carefully studies its compatibilities,

and non-compatibility, its adjuncts, &c., and unconsciously, it may be, discriminates between the types of patients who are or are not susceptible to it. He knows what it can and what it cannot do. He then perhaps writes in praise of it, but in writing, fails to analyse or detail all the thousand-and-one little helps which made the drug in his hands a success. The next man who takes it up may be greatly disappointed with it in the first few cases, and discards it altogether. It thus happens, that many prescriptions valuable in the hands of one, are valueless in the hands of another doctor.

Thomas of Liverpool invented a splint for hip-joint disease; in his own hands, it was a wonderful success. He brought it before the profession, and it was tried in several institutions, but without exciting much enthusiasm in its favor.

Thomas sent for some of these splints made elsewhere, and found that while *very like his own*, they differed so much in principle, as to be thrown aside by him as useless caricatures. Some of these caricatures he pictured in his book; the secret of his own success lay in *personal* supervision of their manufacture in a room in his own house.

It is this *personal* factor of the enthusiasm and individuality of the doctor which contributes to the success of the special prescription. After all, it may be not so much the prescription, but the regimen, dieting, &c., which go along with it which should obtain the credit. But give the same doctor an unfamiliar and untried drug, and the chances are that there will not be the same success. The prescription which he knows intimately, calls out all his other resources and he attacks the case hopefully.

I think it is BRALE who notes a case of a fortune being built up in London by a doctor whose chief prescription had for its main drug, acid-nitro-mur-dil.

The main danger to young practitioners is an exaggerated faith in this or that drug or prescription.

I have come across many who rattle off a patient's complaint in this fashion:—Diagnosis,—neuralgia. Treatment—Calabar bean extract; and some well-known authority is quoted. It is more showy and impressive at first to the patient, but the result is frequently bad, both for patient and doctor, and a good drug gets a bad name undeservedly.

In this plan of prescribing, one great factor is omitted, that is to say, the man himself. If the doctor remember that the patient is a man with a something individual in him in addition to the disease, and if he can get a fair idea of this something, be it habit, temperament, idiosyncrasy or peculiarity, he will be well on his way to writing a sensible and effective prescription and doing his patient good.

To the doctor himself acting on such principles, there would be more confidence in what he prescribed and a greatly diminished itch for new remedies.

The water of the tanks in Secbore, Howrah, and the adjacent villages having been found poisonous through an accumulation of filth and dirt, the inhabitants have been prohibited from using it.

A MIRROR OF PRACTICE.

BRIEF NOTES OF TWO CASES OF SUN-STROKE WITH REMARKS.

By ASST. SURON. PURNA CHANDRA DASS GUPTA,
Kishoreganje.

SUNSTROKE, *insolatio*, *coup de soleil* and heat apoplexy, are synonymous terms, implying the various conditions of one and the same disease. This disease, though common in tropical climates, is very rarely met with in civil practice in India. During a period of about 22 years' practice, I have had the opportunity of seeing and treating only two cases of this disease, (in Lower Bengal), brief notes of which I herewith append:—

CASE I.—C. N. ROY, a Hindu male, of Brahmin caste, aged about 40 years, a priest by profession, of temperate habits, was suddenly taken ill with high fever, temperature 106°F, pulse 100 (full and bounding but soft), respiration quick, shallow, 30; conjunctive blood-shot, pupils contracted. Is partially unconscious and incoherent; no abnormal sounds in the chest; bowels rather costive since last two or three days; general health not good; spleen enlarged, almost reaching to the umbilicus from repeated attacks of malarious fever in his younger days. At some religious festival, he partook rather freely of some melons and other indigestible food, and then walked up to his house under the burning sun of May, a distance of about four miles, when he fell down suddenly immediately after his return home. The weather was moist and sultry. I was sent for at once, and found the patient suffering from the symptoms detailed above. An emetic with a cathartic enema was administered, while application of cold water to the shaven scalp and wet-sheet packing were resorted to, but all proved unavailing. The patient gradually became comatose, which condition deepened and stertorous breathing supervening, the patient expired with two or three attacks of general convulsions within six hours of the commencement of the attack.

CASE II.—BABU S. N. CHATTERJI, a Hindoo male of Brahmin caste, aged about 45 years, a Deputy Magistrate in Government service, very corpulent with short neck, &c., and to all appearance, a fit subject for apoplectic attacks with suspicious scars on both legs, addicted to alcoholic drinks (though not to excess), was suddenly taken ill with high fever on the 28th of April 1894. He had taken a heavy meal of sweatsmeats, &c., on the night of the 25th, and complained of indigestion and weakness on the two following days. I was sent for at 6 A.M. on the 28th and found the patient suffering from the following symptoms:—

Patient very restless, and rolling about in bed; temperature 104°F; conjunctive highly injected, pupils normal but inactive. Breathing hurried and shallow, about 50; perfectly conscious, answers questions rationally, but memory is defective; pulse full, bounding, rather hard, about 100; slight dulness on percussion all over the chest on both sides, respiratory murmur harsh and blowing in character. There is no headache or delirium. A full dose of antifebrin was given at once, with application of cold water to the shaven scalp and constant fanning, while dry cupping over the chest and nape of the neck, and other measures to reduce the temperature and congestion of lungs and brain proved

Intermittent: Hypodermic injection of quinine and wet sheet packing were being prepared, when suddenly the patient, in spite of my urgent orders to think of the recumbent posture, getting to go to stool, and fell down insensible in the verandah. Consciousness was, however, partially restored by sprinkling cold water on the head and face, but the breathing became more and more hurried and shallow, and the patient expired at 10 A.M. (that is, about 7 hours after the commencement of the attack) asphyxiated; the pulse remaining full and strong to the last.

Remarks.—From this brief sketch of the mode of attack, symptoms and termination of these two cases, it appears that the first one was a typical case of sunstroke (*coup de soleil* or heat apoplexy) and that the second a typical case of that variety of the disease called *heat asphyxia*. In the first instance, the cause of attack was no doubt direct exposure to the sun's rays. There was in both, evidently a strong predisposition to the attack from a deteriorated condition of the blood. In the first case from malaria, and in the second from constitutional syphilis and intemperate habits, while a heavy meal was the exciting cause in each case. It is said that soldiers with tight clothing and heavy accoutrements directly exposed to the sun's rays while marching are most frequently attacked with sunstroke, but from these two cases it is manifest that direct exposure to the sun's rays is not the only factor in its causation. Heat apoplexy may be caused by sultry and oppressive weather, without direct exposure to the sun. A deteriorated condition of the blood, arising from whatever cause, is essentially the most potent of predisposing etiological factors. Malaria, syphilis, alcoholism and kidney disease are by far the most frequent causes of such blood deterioration, and it is for this reason that European soldiers are more frequently attacked than native soldiers; for this reason also that the cultivators, who work in the fields under the midday sun, are so easily attacked with this disease. Over-crowding, bad ventilation and deficiency of drinking-water are also mentioned as predisposing causes.

In most works on medicine, three varieties of the disease, namely, the cardiac, the cerebro-spinal and the mixed form are mentioned. The first variety is said to end in speedy death by syncope, the second by coma and convulsions, and the third by a combination of both. In my first case is seen the second variety of the disease, but my second is quite a distinct form, which some authors describe as "heat asphyxia," and which should be considered as fourth variety of the disease. That the over-heated blood acted as a depressant to the respiratory centre in the medulla was very clearly seen in this case. I have never seen a case of the pure cardiac variety of sunstroke in which death takes place speedily by syncope. In such cases, whether the over-heated blood kills by its depressant action on the circulatory centres in the medulla, or by acting directly on the cardiac ganglia, is a question which requires to be decided; as for myself, I think the latter to be more probable; for in my second case, where death was caused by the depressant action of heat on the respiratory centres, no effect was apparently produced on the heart, except in so far as quickening its action, as is commonly seen in all cases of hyperpyrexia, yet both the

respiratory and circulatory centres of the medulla are so close to each other.

It is very difficult to understand how the same amount of heat in the blood, which could paralyse the respiratory centres, leaves intact the circulatory ones, and even stimulates them.

Physiology teaches us that over-stimulation of a nervous centre causes exhaustion in the long run, so it may be assumed here that both the respiratory and circulatory centres were previously stimulated by the over-heated circulation, and that the respiratory centres failed before the circulatory ones.

As regards the *diagnosis* of these two cases, walking under the direct rays of a summer sun in sultry and oppressive weather for four miles after a heavy meal and the sudden attack of hyperpyrexia with severe nervous symptoms were too palpable to mistake it for any other disease than sunstroke in my first case; but my second case presented many points of difficulty. The previous history of exposure, and sleeping in the verandah till a late hour in the night, the high temperature, the rapid breathing and dulness over the lungs, with harsh and blowing respiratory rales, were likely to lead one to mistake it for a case of pneumonia, specially in such a corpulent subject, and in whom a thorough examination of the chest was almost impossible for the extreme restlessness of the patient; extreme congestion of the brain, with redness of the conjunctivae and delirium are commonly found in many cases of pneumonia.

The only means of a differential diagnosis being made, was the history of suddenness of the aggravation of the symptoms. Pneumonia could not have advanced so far within 3 hours from the commencement of the attack, yet pneumonia in such corpulent subjects is not infrequently found to have commenced so insidiously, as not to have attracted the attention of the patient, or of the medical attendant until it had advanced to the point of suffocation, so that the only *reliable* means of making a differential diagnosis, lies in a *thorough* physical examination of the chest. A careful observer can rarely fail to detect the dulness of hepatisation from that of mere congestion, and the blowing tubular breathing of the former from the harsh and blowing rales of the latter condition; fortunately the indications for treatment would be almost alike in both diseases, namely, the removal of the congestion of the lungs and brain and abstraction of heat from the over-heated blood by application of cold douche, wet-sheet packing, cathartics, antipyretics, dry cupping, &c., &c. Stimulants are as a rule, not required in such cases, and if required at all, much discrimination is necessary in their administration. Hypodermic injection of quinine is much extolled in cases of sunstroke. I have however had no experience with it, nor had I the time or opportunity to try it in these cases.

The *post-mortem appearances* in sunstroke are said to be: fluidity of the blood, congestion of the brain generally, and extreme congestion of the lungs, with dilatation of the right heart. But the peculiar appearance of *blisters* after a few hours of death all over the body is a phenomenon not mentioned in any of the books to my knowledge. It is said that the temperature may rise to 111°F or more, and may continue to rise after death for some time, in fatal cases of

heat apoplexy. But the question is, can it rise to such an extent as to cause blisters to rise on the body by the natural process of cooling by radiation, evaporation and conduction, after death?

In cases where there is a history of direct exposure to the sun, it is easy to understand how the blood gets overheated, but where there is no such history, it is not so easy of elucidation. In order to explain the phenomena presented in such cases, the assumption of the existence of a thermo-genetic, thermo-toxic and thermo-lytic centres in the nervous system becomes the more necessary, for without such a theory, we cannot explain how the mechanism of sustaining a uniform temperature in the human body, placed under a variety of circumstances as regards climatic and dietetic changes, can be so easily disturbed, either by direct exposure to solar heat or by a high atmospheric temperature.

Sunstroke, I consider, is nothing but a form of fever. The disease termed "sun fever" and some forms of simple continued fever are but milder forms of this disease.

The nomenclature is, in my humble opinion, wrong in styling this disease, sunstroke, (heat apoplexy or *coup de soleil*). A case of any other fever with nervous symptoms might just as well be called "fever apoplexy." The generic term "sun fever" (ending in death by cerebro-spinal symptoms, syncope or asphyxia), seems to me to be the more appropriate term by which to designate this disease.

—:O:—

A CASE OF PUERPERAL FEVER OF ABNORMAL DURATION.

By ASSISTANT SURGEON. H. D. PANT, I.M.S.,
Gonda.

Mrs. B. M.D., a Kashmiri primipara, *æt.* about 23, was delivered of a dead fœtus on the 12th December 1894. Slight fever came on on the 15th, ushered in by shivering. I was called to attend her on the 21st. Her temperature was then 102° 8 and had been 106 the previous evening. Pulse feeble, quick, 120 per minute. General condition very low, tongue dry and teeth covered with sordes. She was having rigors two or three times a day, and complained of severe neuralgic pain in the left hip joint, extending downward to the knee. She remained under my treatment till the 17th February 1896, and up to the 8th February the rise in temperature was so irregular and fitful, and was so modified by various antipyretic medicines, that it is difficult to make out a regular temperature chart of any clinical value.

To begin with, ordinary fever mixture was prescribed with spirit vin. gallici and an application of chlorate of potash and glycerine to the tongue and lips. Fever continuing, tincture warburghii in 5ii doses every two hours, was given next day. The same was repeated on the 23rd and 24th, along with a mixture containing potash chlorate and tincture digitalis. No improvement in the fever, but the pulse became stronger and the slow typhoid condition disappeared. The discharge from the womb was offensive, and an ulcer was detected in the vagina. Douching with Condy's fluid and applications of iodoform ointment to the ulcer were prescribed. From time to time large offensive clots and shreds were removed from the womb by

the female Hospital Assistant, who was also in attendance. On the 30th, salicylate of soda in 10-grain doses every four hours was tried.

By the 1st of January, the patient had lost much strength, high temperature continued, and the next day, cough with streaks of blood in the phlegm appeared, with great pain on right side of chest and on the back. The patient was troubled with vomiting, and on examining the chest, pneumonic consolidation of the lower half of the right lung was detected, and by the 7th, the base of the left lung had also become congested. Various kinds of cough mixtures with digitalis were tried for relief with local applications of turpentine and poultices. By the 15th January the expectoration became purulent and offensive. A mixture containing ammonia carb. liq. strychniæ and tincture digitalis was given with creasote pills. Gradual amelioration took place in the condition of the lungs, but on the 21st, congestion and enlargement of the liver set in with symptoms of perihepatitis, causing great dyspnoea and restlessness. The spleen was also enlarged and tender. Quinine in 10-grain doses was occasionally given, but no medicine seemed to have any permanent effect in reducing temperature, which was persistently high. The case was now getting serious day by day.

Bed sores appeared, and the patient was reduced to skin and bone; severe neuralgic pains continued notwithstanding treatment, and low typhoid symptoms supervened. Having tried almost every available drug without much benefit, I resolved on the 30th to try the effects of large doses of quinine sulph. I accordingly prescribed 20 grains of the drug dissolved in acid hydrobrom dil. with 20 drops of chlorodyne in an ounce of water, to be given four times a day. This time the result was a little more encouraging. On the night of the 2nd February, the patient had an unusual hysterical fit. She seemed, all of a sudden, to have gained great strength of body and mind, got up from the bed by herself for the first time since her confinement, moved about, danced and sang, and gave minute details of the occurrences of her childhood which it was believed, she had long forgotten. The result of the night's fit was, that next morning the patient complained of severe pain in the right hip-joint and over the sacrum and coccyx; there was some swelling too, which lasted for about a fortnight. From the 3rd, the quantity of quinine was reduced to 15 grains four times a day. On the 9th the temperature became normal and remained so onward.

Remarks.—It is needless to say that antipyrene or phenacetine had to be given pretty frequently during this protracted illness, and the patient's constitution was supported by liberal nourishing diet and brandy. For full 56 days, she was under the influence of high fever. Hopes and fears alternated. The case was diagnosed and treated from the outset as one of puerperal septicæmia; but I cannot help thinking that there was a strong admixture (more particularly towards the latter part), of malarial poison of a remittent type.

Dr. John Murray reports a case where a boy, *æt.* 17, in an advanced stage of phthisis, used his saliva to mix some pigment with which he tattooed the arms of three other lads, and thus inoculated them with *tuberculosis*, bringing on painful swellings that persisted for a long while, in their axillary glands, while inflammation, swelling and small pustules appeared along some of the tattooed parts.

TWO CASES OF VESICAL CALCULUS: MEDIAN LITHOTOMY: RECOVERY.

By HARRY GIDNEY, D.M.C.C.

Assistant Civil Surgeon, Mysore.

CASE I.—Child aged 2½ years, hill tribe, entered my hospital suffering from all the symptoms of vesical calculus. On examination with a THOMPSON'S sound I detected a stone lying at the base of the bladder. I intended performing a litholapaxy but found that the urethra was too small. Lithotomy was the only other alternative. I had intended performing lateral lithotomy, but could not, owing to there being no lateral grooved staff sufficiently small for use, hence I was compelled, though very reluctantly, to resort to median lithotomy.

The patient was put under chloroform, and a median grooved staff was introduced. I made a median incision, extending from the under surface of the scrotum to the "edge" of the anus. After dividing the superficial soft parts, I pushed the knife on until it impinged against the groove in the staff, it was then pushed, guided by my index finger, until it came upon the prostate, which I notched with the edge of the knife. I then withdrew knife and staff, bearing my index finger still in the wound, but on attempting to introduce the lithotomy forceps, found the parts too small to receive it, and by this time I discovered that my finger had penetrated into a false passage between the anterior wall of the rectum and the bladder. I had lost the path into the bladder. I was thinking seriously of leaving the case alone, when, as a *dernier resort*, I determined to find my way back again by exploring with a blunt-pointed probe. After a careful search for about a quarter of an hour, I came upon the path, and guided by the probe, I passed an ordinary dressing forceps with little or no difficulty, into the bladder. I then opened the blades and caught the stone in its long axis. Finding it to be rather large for the grasp of the dressing forceps, I broke it into two pieces and then extracted the two fragments piece-meal, by means of the dressing forceps, making a slight rotatory movement during the extraction.

A catheter was now introduced through the perineal wound into the bladder (which was washed out with warm boracic lotion, 1 in 40) and left in. All hæmorrhage was arrested, the parts washed antiseptically, &c., and dusted with iodoform and covered over with some boracic ungt. smeared on lint.

The case made an uninterrupted recovery, and was discharged, quite cured, on the 13th day after the operation.

CASE II.—Child aged 2 years, hill tribe, came into the hospital, having all the symptoms of vesical calculus.

All further particulars in this case are identical with those in Case No. 1, (except that there was a good deal of hæmorrhage, which took me a little time to control), it is therefore unnecessary to recapitulate them. The little patient made a complete recovery; the wound healing up by the twelfth day after operation.

Remarks:—(a) The parts in both cases were so small that the lithotomy forceps could not be used without fear of bruising the neck of the bladder. I had therefore to resort to an ordinary dressing forceps, which answered the purpose just as well. The only difficulty I experienced whilst extracting the stone was, that owing to the blades of the dressing forceps being so small, and not concave,

a firm hold of the stone could not be got so easily, and the stone in consequence slipped from the grasp on one or two occasions.

(b) The difficulty experienced in the after-treatment in both cases (especially in Case I.) was, that the catheter constantly came out, the child being so restless. This to a certain extent I remedied by tying the two knees together with a firm bandage.

(c) The danger likely to arise when one gets into a false passage (as occurred in Case I.) demonstrates the cardinal rule, "never to withdraw the staff until we are certain that the index finger is within the neck of the bladder."

(d) Litholapaxy and lateral lithotomy are operations to be preferred in children; but I was precluded from performing either, by reasons already given.

INJURY TO HEAD CAUSING LOSS OF SPEECH FOR DAYS: RECOVERY.

By ASST. SURGN. ROMANATH DE, M.B.,

Madaripore.

PANCHU, a Hindu male, aged 30 years, was brought by the police into hospital, on the 14th March 1895, with a swelling on the front of the head, said to have been caused by being struck with a piece of bamboo.

Condition on admission.—There was a large swelling on the middle of the front of the head which pitted on pressure. The patient was quite conscious, could move about easily but could not speak at all. No paralysis of any of the organs. Conjunctivæ slightly congested. Pupils normal.

Previous history.—The patient, after recovery, stated (which statement was corroborated by that of his father) that on the 12th March, i.e., two days previous to his admission into hospital, he was struck in a field close to his house by another man (with whom he had had some dispute about a piece of land), on the head by a thick bamboo, from the effect of which he immediately became unconscious and fell down. He was then removed to his house, and after an hour or so, recovered his senses, but lost the power of speech completely.

Treatment.—I kept him under observation for a couple of days with cold application to the head. On the third day, I gave him an opening medicine, consisting of 20 grains of pulv. rhei. co., and 3 grains of calomel, which thrice moved him freely. On that day, the swelling on the head subsided completely, but there was not the least improvement in the power of speech. On the following day I gave him 3 grains of iodide of potassium with an ounce of infusion of chiretta to be taken thrice daily. He continued in the same state, till the 24th March, i.e., the eleventh day of admission, when for the first time I noticed that he could speak, though very indistinctly. There was great improvement on the following day, and he made an uninterrupted recovery till the 29th of March, when he was discharged perfectly cured, after having been in the hospital for 16 days.

Remarks.—The case is a unique one. I have never come across one similar to this during my student-life, nor during the whole course of my professional career extending over a period of 10 years, both in Bengal and Burma, nor am I aware whether any of your numerous readers have met with a like experience. It is evident that there must have been some injury to the 3rd left frontal convolution (Broca's), which interfered with the faculty of speech, but the wonder is that along with this there were no other symptoms of cerebral derangement.

OUR PICTURE GALLERY.

MISS FLORENCE DISSENT, M.B.

L.B.S.P., L.M.S.S. (Edin.) L.V.P.S. (Glas.)

THE portrait which embellishes our "Picture Gallery" is that of a young lady, whose career has been one of such marked success as to afford a striking illustration of what can be accomplished by patient self-denial on the part of Anglo-Indian parents with only limited means at their command, and by resolute perseverance on the part of children, born and educated for the most part in this country.

MISS FLORENCE DISSENT, the subject of our notice, is the youngest daughter of Mr. C. E. DISSENT, a prominent and widely-respected member of the Anglo-Indian community. She was born in Calcutta on the 8th of July 1869, and received her early training at home under the direction of her parents, who, she gratefully acknowledges, laid deep the foundation of the successes she has achieved in her distinguished academical career. At the age of eight, she was entered as a day-pupil in the Loretto Convent in Middleton Row, Calcutta, where she continued to the age of fourteen. Her father having in the meantime been elected a member of the Committee of Management of the Doveton College, she was transferred to the Doveton Institution for young ladies. There she remained until the year 1886, when a great and good work in India was set on foot by the noble lady, whose name will ever remain associated with the movement. We allude to the establishment, under the auspices of the Countess of Dufferin, of classes in the Medical College for the training of lady doctors to enable the women of India to obtain medical aid from those of their own sex. Mr. DISSENT was among the first to recognise the possibilities which this movement was calculated to open up to young women born and educated in this country, of attaining to an honorable independence. Accordingly, at the instance of her father, Miss DISSENT now determined to direct her energies to the study of medicine. Having easily passed the preliminary test required by the regulations, she was enrolled in March 1886, on the books of the Calcutta Medical College. At the conclusion of the four-year course, she obtained the gold medal for medicine, four honor certificates for proficiency in dentistry, hygiene, ophthalmic medicine, and pathology respectively, and the diploma of the College. Her success as a student did not escape the keen observation of Dr. J. M. COATES, the Principal of the College, on whose recommendation Miss DISSENT was at once placed in medical charge of the hospital and dispensary for women at Naini Tal, a post she held for seven months. In recognition of her services, the Naini Tal Committee strongly recommended Miss DISSENT to their Central Branch, and she received the important charge of the Allahabad Dispensary and Hospital, then recently opened. For two years Miss DISSENT discharged, with conspicuous ability and success, the onerous duties connected with this, one of the largest of the Dufferin hospitals in the North-Western Provinces and Oudh. In addition to the usual routine of hospital work, Miss DISSENT rendered material help to the Civil and Assistant Surgeons in training a large class of nurses by giving them lectures and practical demonstrations in the wards. On her health threatening to break down, the Allahabad Committee marked their appreciation of Miss DISSENT's services, by sending her for four months to Naini Tal, when she once more resumed her old charge. The Naini Tal branch was anxious to obtain her services permanently, and with this object in view, offered her liberal terms; but about this time an opportunity was afforded her of proceeding to Europe to further her medical studies. She left India in March 1893, and after a temporary rest enjoyed on her by the medical authorities in London, Miss DISSENT was admitted in October as a student in the London School of Medicine for Women. On completing a course of three months, during

which she walked the wards of the Royal Free Hospital, Gray's Inn Road, Miss DISSENT proceeded to Edinburgh to prepare for the triple qualification of the Royal Colleges of Edinburgh and Glasgow. She appeared for this examination in April 1894, and so well did she acquit herself in it, that we hear some of her papers were read out by the professors to the class of male students in the Edinburgh College. Having now obtained the triple qualification of L.B.C.P. and L.R.C.S. (Edinburgh) and L.V.P.S. (Glasgow), Miss DISSENT finally passed over to Brussels, when she obtained the degree of Doctor of Medicine with distinction, in May 1894.

MISS DISSENT has recently returned to India, and we are glad to learn that she has been offered a first-grade appointment at Ulwar in connection with the Dufferin Institution for the employment of lady doctors.

This little biographical sketch affords food for serious reflection. We see here energy of action and perseverance leading to pronounced success. But underlying these, is the united action of the parents, both solicitous for the welfare of their child, both working towards the same end, and loyally helping each other to attain the same object.

We have gone out of our usual routine in honoring Miss DISSENT with a place in our Picture Gallery, which has hitherto been reserved for members of our profession, whose length of service, or experience of tropical disease, other special qualifications, which have been of material value to the country and the State, have called for some special mark of public appreciation, such as our gallery affords, but we feel that no apology is needed in placing Miss FLORENCE DISSENT in the honored position she now occupies among our illustrations of "the worthies" of our profession. The occasion offers an object lesson to which we would draw the pointed attention of our domiciled European and Eurasian confreres, who have grown-up daughters for whose future welfare they must of necessity have many anxious cares. It is seen pretty commonly around us that now-a-days young ladies cannot look to marriage as the certain consummation of their hopes and that unless the means of earning an honorable livelihood have been sought after and provided, it but too often happens, that they are left to the mercy of the world and the world is cruel enough to the helpless and friendless. We are constantly appealed to on behalf of the daughters of medical men in India, who are left unprotected for at the death of their parents, and the sad fact brings home the conviction that in many instances a noble and substantial provision against such calamities could easily and effectually have been at hand, were the helpless and grown-up orphan girls prepared by special education and training during the lifetime of their parents, to earn their own living. Many avenues of work are open to our girls, but none offers so splendid an opportunity for usefulness to women in any other part of the world, as medical practice by women among the women of India. The zenanas will remain closed to men physicians for another century, and all this while women physicians have to themselves an unexplored field of service that is unsurpassed in its possibilities for doing good. It is to the Dufferin Fund Service and to the independent practice of medicine among the women of India that we earnestly desire to direct the attention of medical parents. Miss DISSENT's excellent success will, we sincerely hope, urge many European, Eurasian and Indian young ladies to follow her footsteps and emulate her example.

Chloroform inhalations &c. in 3II to 3III quantities per day supplemented by hot baths and sometimes by morphia subcutaneously, gave P. A. Probramsky excellent results in the treatment of acute trismus, the spasms ceasing and the muscles relaxing, while the pulse becoming stronger and slower, and the respiration deep and regular, the patient fell into a quiet sleep of several hours' duration.

*Yours Sincerely
Florence Lisant*

THE Indian Medical Record.

1st May, 1895.

TYPHOID FEVER: ITS CAUSE AND TREATMENT.

THERE has been not only in India but it may almost be said universally a growing interest in all matters relating to typhoid fever. Much of this interest and of the increased concern of the profession with this disease is, no doubt, a part of the profession's revision of its knowledge of diseases in general, such revision being the necessary result of the germ theory of diseases. It will not be amiss then to embody some of the opinions and experiences contributed to many of the journals of the day on the causes, symptoms, and treatment of enteric fever. As to its cause, it is maintained by some that a certain bacillus is peculiar to this disease alone, it is said by others that the bacillus is none other than the *bacterium coli communis* of the large intestines which under certain conditions invades the small intestines and multiplies there. Conversely then, while on the one side sewage, filth or anything else taken into the system cannot cause typhoid fever, save and except they contain the specific germs of typhoid, on the other, they may serve as nurseries for the growth, reproduction, and migration from their habitat of the *bacteria coli communis*. DR. ERNEST HART is of opinion that the typhoid germ in India and warm climates has a different history from what it has in England; in the former case epidemics of typhoid appear to arise *de novo*, while in England they seldom or never do; in other words, in England the typhoid germ, though able to live for a time as a saprophyte to exert its virulence only after resuscitation by passing through the human body, but in certain warm climates the germ is a genuine saprophyte, retaining its virulence as an inhabitant of the soil, and not needing "periodical resuscitation in the human body to confer on it pathogenic properties." These views are also held by DAVIDSON and by HUNT with reference to typical cases of typhoid in North Queensland, by CRAWFORD of the occurrences of the disease in Afghanistan, and HOFF in the United States. Hence in these countries sanitary measures are infinitely less efficacious than in Europe in preventing the disease, and herein is supposed to lie some explanation of the prevalence of typhoid among young soldiers in India. Whether however the germs, whose activity and reproduction are causative of the disease, have their habitat in the soil or in the human system, there is much reason to believe that certain atmospheric conditions and influences develop or increase their pathogenic properties.

Treatment.—We cannot do better than begin this compilation of opinions on the treatment of enteric fever with the remark of SIR WM. BROADBENT, M.D., of St. Mary's Hospital, London, *viz.*, that "there is no better test of clinical sagacity and capacity than the conduct of a case of typhoid fever." It is very important that a diagnosis be arrived at as early as possible, and that from the very commencement of the treatment the most absolute rest, physical and mental, be strictly enjoined. The management and treatment of a case of typhoid fever may be divided into three heads, *viz.*, the (1) hygienic, (2) the dietetic,

and (3) the therapeutic. There are no special remarks to be offered with regard to the first of these; but for the carrying out of the details under this and the other heads the provision of thorough, well qualified, and efficient nursing cannot be too strongly insisted on. The patient's room should be well ventilated, the temperature of the room should be even and agreeable, and a moderate amount of natural light admitted into it, everything should be done to make the surroundings as conducive as possible to quiet and repose. All excreta should be promptly removed and thoroughly disinfected.

The dietetic management of a case of typhoid is one that demands a deal of discrimination and observation. SIR WILLIAM BROADBENT remarks: "An absolutely indispensable guide to the feeding of a patient is regular and systematic inspection of the dejecta. This is the secret of success in the treatment of typhoid fever." Almost all are agreed that good milk is positively the best food for typhoid cases, and three pints of it should ordinarily suffice. Eight ounces may be given every three hours. The addition of lime water or of soda water is generally recommended, and this addition is particularly necessary if the evacuations contain curds, however finely divided. If the patient dislikes milk, beeftea or meat extracts may be substituted; and the return to eggs, toast-bread and vegetables must be very cautiously allowed and regulated after the temperature has fallen to normal for five or six days. The matter of the administration of stimulants has always been one on which there has been much difference of opinion, and perhaps it will ever remain one which will demand very judicious observation. The points of agreement on this matter appear to be that they are seldom if ever required at the early part of the disease, but are called for when there is exhaustion of the nervous system, failure of the circulation, or failure of digestion. DR. BROADBENT'S advice is that they be given when there is frequency and low tension of the pulse, mental confusion, dryness of the tongue, and prostration; and they may be assumed to be acting beneficially if the pulse-rate is lowered, the temperature somewhat reduced, the nervous system steadied, and more restful sleep secured under their influence. The persistent odour of alcohol in the breath is an indication that the stimulant is doing harm. Drunkards and habitual alcohol consumers are better by abstinence and strychnine or nuxvomica. The stimulant should be given with the nourishment. Two or three ounces of brandy in divided doses should usually suffice, and ten ounces may be taken as the maximum which may be given with benefit and safety in twenty-four hours.

Ought we to medicate? This may appear a strange question, but one at the same time quite legitimate, when we consider that it is easy in this disease to commit ourselves to harmful medication, for DR. CASLAR believes that the disease "is not to be treated by medicines." The wide range of remedial agents recommended and the different plans of treatment advocated may be reduced to two heads:—(1) antiseptic and (2) antipyretic. Considering that the disease is due to a poison, and that the symptoms are the result of that poison on the system, it is reasonable that our efforts should be directed towards eliminating or destroying that poison, and towards counteracting its toxic influence. DR. BROADBENT points out that

though the typhoid microbe, soon invades the blood and tissues, where it is improbable that they can be destroyed without serious injury to the blood and tissues, yet it must be remembered that the bacteria exist in the intestinal tract, where by their action, they produce other septic material. For this and other reasons the old management of a case of typhoid in the initial stage, has undergone quite a change; for whereas the administration of a purgative was religiously avoided about twenty years ago in the early stage of typhoid, English and American authorities have begun to pin their faith on the benefits of calomel advocated by LEIBERMEISTER, on the administration of purgatives early, and on high injections for clearing the intestines of useless and harmful matters. Salol, the mineral acids, nitrate of silver, quinine, iodine, sulpho-carbolates, and a host of other medicines have been used as intestinal antiseptics with varying good effect; but Sir Wm. BROADBENT lauds the perchloride of mercury as the most efficacious, and advises its use in one drachm doses of the solution with one grain of quinine every 3 or 4 hours for a day or two. Pepsine and the mineral acids appear to prove very beneficial. The purgatives and antiseptics alluded to, by clearing out and disinfecting the alimentary canal, mitigate nervous symptoms and intestinal irritation; so that maniacal delirium, stupor, diarrhoea, and abdominal distension are relieved by their use. Tympanitis, which is always a painful accompaniment of the disease, is said to be kept off by the above-mentioned antiseptic forms of treatment. Acute tympanitis, whenever occurring, is always a sign of danger, and is best relieved by half drachm doses of tincture of opium. Bleeding from the bowels is stopped with ice bags over the right iliac fossa, subcutaneous injection of ergotine, and full doses of opium. The only chance for the patient in case of suspected perforation is the fearless use of opium. Insomnia in typhoid is a condition which often taxes the medical attendant's resources, and of the various medicinal agents employed to combat with this symptom, Dr. BROADBENT considers phenacetine and antipyrin depressing and hence mischievous, chloral lowering to the heart's action, bromides seldom of real service, and a preparation of opium or of morphia the most serviceable. It is more or less generally conceded that every effort should be made to relieve hyperpyrexia, no matter in the course of what disease it may occur, and perhaps it is as to the means to be employed for the reduction of temperature that there is the greatest diversity of professional opinion. Antipyrin, phenacetin, and powerful antipyretics of this ilk, which were once thought to supply all that was needed to reduce body heat, are fast losing favor, and have but few advocates, particularly as to the advisability of their employment in the hyperpyrexia of typhoid fever. Dr. BROADBENT speaks of these remedies not only as failures, but as positively harmful; and ROQUE and WALL have found that "antipyrin arrests the elimination of toxins by the urine without preventing their formation." Our American brethren, however, still advocate their employment in moderate doses, cautiously given and in combination with stimulants. The application of water in one form or another is in general favor. Cold or tepid sponging of the body seldom fails to afford comfort. With American practitioners, the bath

used in all detail after the method of Brand, is so very extensive and giving favor, but most of them now warn against the disadvantages and expense of its employment in private houses. Statistics both in American and English fever hospitals, however, show that by its adoption typhoid mortality has been reduced to 5 per cent. and under. The continuous abstraction of heat by water is spoken highly of by Dr. BROADBENT. This is the method adopted by Dr. BAER of the Northern Hospital at Liverpool, who uses the continuous bath for the more severe cases, and wet compresses to the abdomen in the slighter ones.

MISAPPLIED POWER BY THE CALCUTTA HEALTH OFFICER.

IN his zeal to leave no stone unturned, Dr. SIMPSON, the Health Officer of Calcutta, has caused the following notice to be affixed to the gates or compound walls of houses in which Municipal Inspectors have reported to him that persons afflicted with small-pox were resident:—

"You are hereby informed that by remaining in you are spreading or likely to spread contagion of small-pox; and you are warned that unless you within 12 hours remove yourself to Hospital, you will be prosecuted before a Magistrate under section 269 of the Indian Penal Code.—W. J. SIMPSON, M.D., HEALTH OFFICER."

In applying this threat, no consideration has in any case, as far as it has been brought to our notice, been shown for the circumstances of life of the sufferers, nor of their environments. We pointed out in our last article on the recent small-pox epidemic in Calcutta, that incompetent Municipal Inspectors had in some instances reported cases of chicken-pox as cases of small-pox. Of this fact we do not write from hearsay alone, but from actual personal knowledge. Ignorance displayed in the matter of the diagnosis between a benign and a malignant disorder is fraught with the most serious and disastrous consequences. The Campbell Hospital, which has sheltered the victims of small-pox, makes scant provision for the differentiation and segregation of cases of varying type and virulence. Thus when the modified, the confluent and the malignant forms of the disease are herded together, in obedience to the law of contagion, they may readily react on one another, and thus the victim of a simple, and almost harmless, febrile eruptive disorder may speedily absorb the more deadly germs around him and discover that the place of his shelter and protection has consigned him to a fearful and ghastly doom. This may seem but a graphic and tragical picture of the imagination, but unfortunately it is only too true, and accentuates the urgent and imperative need that exists for a contagious hospital, affording accommodation in the arrangement of its wards for the varying degrees of epidemic contagious disease and also for suspicious cases to be kept apart under observation.

In the absence of such a hospital, the cruelty and injustice of the action of the Health Officer in indiscriminately placarding the homes of the people with threatening penal notices, becomes all the more glaringly apparent. We have no desire to accuse the Health Department of the Calcutta Municipality of wanton indifference or of intem-

tioned from meeting, but we have no hesitation in condemning the present practice of compelling people afflicted with small-pox, and much more so of those having some other suspicious form of eruptive fever, under the fear of criminal prosecution to hasten away to a hospital whose scant provision for the medical attendance, nursing and accommodation of the sick, has made it a proverbial charnel house, to leave their comfortable homes and their loved ones, where every care is being exercised not alone for their recovery but where modified and effective segregation, disinfection and fumigation are rigidly observed under the instructions of their attendant family physicians. Another feature of the Health Officer's threatening notices that is extremely objectionable and unprofessional in its arbitrariness, is the fact that such notices, when served upon respectable families, having a doctor in attendance, who is employed in rigidly enforcing all the sanitary precautions to prevent the spread of contagion, ride roughshod over the family physician's professional qualifications and responsible duties, a line of action that is preposterous and proves that the conduct of the Health Officer is not only absolutely uncalled for but distinctly illegal. For there is no power conferred upon the Health Officer by any Act of the legislature which authorises him to worry and annoy and frighten decent people out of their homes, where they are being properly protected and cared for, and where the spread of contagion is being safeguarded under the direction of a qualified physician, forcing them by his high-handed officiousness into imperfectly equipped institutions where a harmless disease is liable to assume a fatal form. It is well that the public should know that "a man's home is his castle," and that Dr. SIMPSON's threats are a vain and arbitrary exercise of mistaken authority, save and except when there is a flagrant disregard for those precautions that are calculated to prevent the spread of infectious disease. We would go further and warn the Health Officer to desist from his present practice of indiscriminately threatening the public, for there is danger to the Municipality in his action, as if it can be proved that by cause of any such notice served on a person suffering with modified small-pox or chicken-pox, compelled by fear of ignoring such notice, to enter the Campbell Hospital, and that while there, such person has developed a malignant form of disease, a claim for serious damages would inevitably lie against the Municipality.

—30—

THE INDIAN MEDICAL ASSOCIATION.

In compliance with the notices issued, the fourth meeting of the Council of the Indian Medical Association was held in its Library on the 17th April 1895. Present: DR. LAL MADHAB MUKERJEE, President, in the chair, DR. E. W. CHANDLER, J. G. ANDERSON, H. C. HODGKINS and J. R. WALLACE. After reading and confirming the minutes of the third meeting of the Council, the following items of business were brought forward:—

1. The Secretary read a letter from the Surgeon-General with the Government of India concerning the memorial from the Association, regarding the grievances of Civil Assistant Surgeons and Civil Hospital Assistants, which memorial is now receiving due consideration at the hands of Government.

2. Read a letter from Surgeon-Captain A. BISHU SRANKA, Civil Surgeon of Jalpaiguri, forwarding an appeal from Mr. ANANTA LAL MANDAL, V.L.M.S., Civil Hospital Assistant of Jalpaiguri, to the Secretary of the Indian Medical Association, requesting the help of the Council to obtain sanction for Mr. MANDAL to appear for the F. A. Examination of the Calcutta University, in view to his graduating L.M.S. & M.B., Calcutta. The appeal was forwarded by the Council with its recommendation to the Vice-Chancellor of the University of Calcutta. The Secretary also read the reply to the above appeal from the Registrar of the University, who stated in reply, that the provisions and rules of the University refer to graduates of the Calcutta University, and not to vernacular licentiates, and therefore Mr. MANDAL's appeal could not be accepted. This decision was forwarded to the applicant.

3. The Secretary announced that the Library of the Association had received a donation of Rs. 500 from H. H. SIR BHAGVAT SINGHI, M.D. K.C.I.E., Thakore Sahab of Gondal and Vice-President of the Association. The Council resolved to send a vote of thanks to His Highness for his princely gift; which has been done.

4. The Secretary proposed the names of sixty-two new members who had applied for admission to the Association since the Council's last meeting. It was resolved that they be duly elected. Their names have been published in the *Record*.

5. In view of the approaching elections to the Legislative Council of the Lieutenant-Governor of Bengal, after due discussion of the matter, the following draft letter was resolved upon and has been submitted:—

From

THE SECRETARY,
Indian Medical Association, Calcutta.

To

THE CHIEF SECRETARY,
Government of Bengal, Darjeeling.

SIR,

In view of the forthcoming elections to the Legislative Council of the Government of Bengal, and having due regard for the power vested in HIS HONOR THE LIEUTENANT GOVERNOR OF BENGAL, to receive the nominations of such associations as His Honor may prescribe as coming within the action of the COUNCILS ACT, I am directed by the Council of the INDIAN MEDICAL ASSOCIATION, to solicit the privilege of permitting a representative of the INDIAN MEDICAL ASSOCIATION, which represents the local medical profession—not only of Bengal but of India and Burma—to have the honor of a seat in the Legislative Council of the Government of Bengal.

In view of the possible sanction of their request, the Council would most respectfully beg to nominate NAI LAL MADHAB MUKERJEE, BAHADUR, L.M.S., F.C.U., Honorary Presidency Magistrate of Calcutta, the President of the Indian Medical Association as their representative.
